Introduction - The Regional Flood Plan in Context

Overview of Establishing Legislation

In Texas, the billion-dollar disaster is becoming a typical occurrence. Between 2015 and 2017, flooding alone caused almost \$5 billion in damages to Texas communities. As the state grappled with how to better manage flood risk and decrease the loss of life and property from future disasters, the Texas Water Development Board (TWDB) led the first-ever flood assessment, which described Texas' flood risks, provided an overview of roles and responsibilities, and contained an estimate of potential flood mitigation costs and a summary of local entities views on the future of flood planning. This assessment was created because:

- Flood risks, impacts, and mitigation costs had never been assessed at a statewide level
- Flood risks pose a danger to lives and livelihoods
- Much of Texas is unmapped or uses outdated maps (*Peter M. Lake, 2019*)

The TWDB presented its findings to the Texas Legislature during the 86th legislative session in 2019. Later that year, the Legislature adopted changes to Texas Water Code §16.061, establishing a regional and state flood planning process led by the TWDB. The legislation provided funding to improve the state's floodplain mapping efforts and develop regional plans to mitigate the impact of future flooding. A mandate required the TWDB to facilitate the creation of a regional flood plan for each of the state's 15 major river basins by January 10, 2023. Updates are required every five years thereafter (*TWDB Flood Planning Frequently Asked Questions, 2021*).

The overarching intent of the plans is to protect against the loss of life and property to:

1. Identify and reduce the risk and impact to life and property that already exists, and
2. Avoid increasing or creating new flood risks by addressing future development within areas known to have existing or future flood risks

Overview of the Planning Process

In 2019, the Texas Legislature passed Senate Bill 8 directing the creation of the first-ever State Flood Plan for Texas—to be prepared by the TWDB and follow a similar region-driven “bottom-up” approach used for water supply planning in Texas for the past 20 years. Fifteen flood planning regions were established—based on river basins. The first Texas Flood Plan will be delivered from Regional Flood Planning Groups to the TWDB by January 10, 2023.

Who Prepared the Plan?

The TWDB has appointed Regional Flood Planning Groups (RFPG) for each region and has provided them with the funds necessary to prepare their plans. The TWDB will administer the regional planning process through a contract with a planning group sponsor chosen by the RFPG for their significant role within the river basin. The sponsor will support meetings and communications and manage the contract of the technical consultant once determined by the RFPG. The Lower Colorado River Authority (LCRA) was selected as the project sponsor for the Lower Colorado-Lavaca Region. The RFPG selected Half Associates, Inc. as the technical consultant to assist with developing the Lower Colorado-Lavaca Regional Flood Plan.

The RFPG’s responsibilities include directing the work of their technical consultant; soliciting and considering public input; identifying specific flood risks; and identifying and recommending flood management evaluations, strategies, and projects to reduce risk in their regions. To ensure a diversity of perspectives are included, members represent a wide variety of entities potentially affected by flooding, including:

- Agriculture
- Counties
- Electric Generation
- Environmental Interests
- Industry
- Municipalities
- Public
- River Authorities
- Small Businesses
- Water Districts
- Water Utilities

The Lower Colorado-Lavaca RFPG is responsible for developing the regional flood plan for the Lower Colorado, Lavaca River, and San Bernard Basins, following the TWDB requirements. The TWDB will combine the regional flood plans into a single state flood plan to be delivered to the Legislature by September 1, 2024.

Funding Sources

To fund projects identified by these plans, the Legislature created a new flood financial assistance fund and charged the TWDB with managing it. The Texas Infrastructure Resiliency Fund, as approved by Texas voters in November 2019, is being used to finance the preparation of these plans and will also be used to finance flood-related implementation projects. Communities that identify future projects aimed at flood mitigation will be eligible for financial assistance through grants from the TWDB.

Draft 7-13-22

Characterization - The Lower Colorado-Lavaca Region

The Lower Colorado-Lavaca Region (Flood Planning Region 10) is comprised of three major river basins, the lower portion of the Colorado River, the Lavaca River, and the San Bernard River basins. The region extends from the northwest near San Angelo to the southeast to Matagorda and Lavaca Bays and the Gulf of Mexico. Major tributaries within these basins include the Llano, Pedernales, San Saba, Lavaca, San Bernard, and Navidad Rivers and Sandy, Onion, Cummins, and Champions Creeks. Major surface water impoundments, some of which have flood storage, include Lake Coleman, Lake Brownwood, Lake Texana, and the Highland Lakes system.

The central portion of the Lower Colorado-Lavaca Region lies within what’s known as “Flash Flood Alley,” one of the most flood-prone areas of the United States. Major storm and flood events can occur throughout the year but are most common during the spring and fall. Much of the region, particularly the lower coastal areas, is exposed to tropical storms and hurricanes with flooding caused by heavy areawide rainfall and coastal storm surge.

The Austin Metropolitan Area is the major population center in the region, with a current population of approximately 2.3 million, the majority of which is in the Lower Colorado-Lavaca Region (*U.S. Census Bureau, 2020*). The region’s population is projected to increase by 50 percent by 2050. In terms of land use, much of the region is rural in nature, with small and medium-sized towns and cities interspersed throughout. The region also includes several public agencies with flood control and drainage responsibilities, including the Lower Colorado and the Lavaca-Navidad River Authorities, Utility Districts, and Drainage Districts.

Figure 1.1 Lower Colorado-Lavaca Region

Figure 1.2 Lower Colorado-Lavaca Region Quick Facts

To better comprehend the nature of that flood risk, this section will cover people, type and location of growth, economic activity, and sectors at the greatest danger of flood impacts.

Social and Economic Character

As the Lower Colorado-Lavaca Planning Region increases in population, communities are expanding outward to accommodate this growth. Texas grew roughly 15 percent in the last 10 years. As structures are built on previous farmland and crops are replaced by urban sprawl, the increase in impervious surfaces generally decreases the absorption of precipitation. Urban drainage systems could also tax the capacity of the Lower Colorado and Lavaca River’s, creeks, and tributaries. Population growth and the outward expansion of urban areas into what was previously open space have increased the burden on the region’s flood control system and are exposing a rising number of residents to flood risk. Floods and other disasters could affect everyone, but they are unlikely to affect everyone equally.

The Lower Colorado-Lavaca Region stretches over 24,380 square miles, 43 counties, and 376 local communities and special districts. It is important to note that the river basins do not neatly follow or conform to county boundaries. The Lower Colorado-Lavaca planning area includes only portions of many of the 43 counties (*Table 1.1*).

Table 1.1 Lower Colorado-Lavaca Regional Flood Plan Counties

*Indicates this county is partially within this RFPG and is also represented by at least one other RFPG.

Population and Future Growth

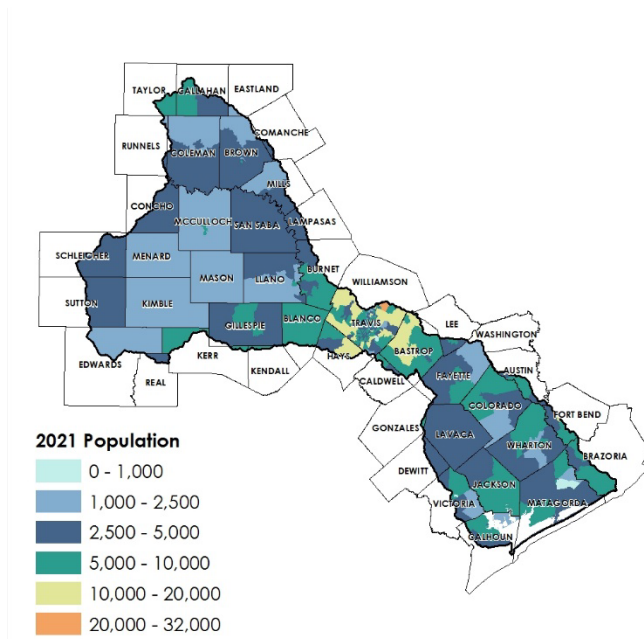

Current Population

The 2020 five-year American Community Survey (*U.S. Census Bureau*) estimates show that the existing population of the region is 1,916,344, which is over 6 percent of the population of Texas. As indicated in *Figure 1.3 2021 Population by Census Tract*, the northern portion of the region is largely embodied within the Texas Hill Country. The Texas Hill Country is characterized by sparsely populated small towns with pockets of populations concentrated in and near downtowns. The largest concentration of residents live in Travis County in the central part of the region. The southern portion of the region is also characterized by smaller population centers embodied within rural counties.

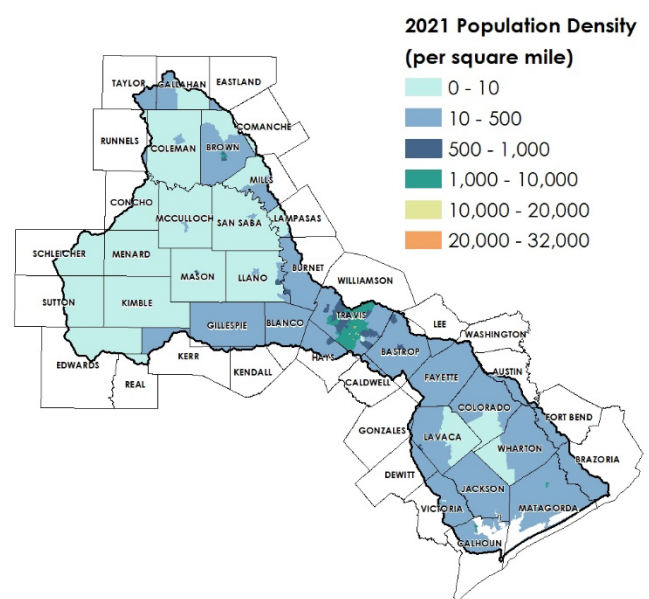

Map 1.3A (Figure 1.3) also shows that the greatest numbers of people, by census tract, are largely located along the major river corridors. This indicates many large cities historically were developed close to water.

Figure 1.3 2021 Population by Census Tract

Map 1.3A

Map 1.3B

Source: U.S. Census Bureau 2021

Population Density and Character of Development

Beyond just total population numbers, the concentration of population density as well as form and character of development also varies widely across the region. *Map 1.3B (Figure 1.3)* shows that the northern part of the region has the lowest density of development (i.e., lowest population density per square mile), and the southern portion is slightly denser, but not by much. Various counties show small pockets of denser development, mostly located around the downtown of cities that serve as the county seats. The central portion of the region, particularly around Austin, has the densest concentration of population.

The form and character of development also change across the region, including changing characteristics between areas of rural, suburban, and urban character, and special considerations for those areas along the coast (*Figure 1.4*). Each of these areas exhibits different characteristics and needs related to flood prevention and mitigation.

In sparsely populated rural areas, flooding often impacts rural roadways, low water crossings, and small downtowns close to major watercourses (e.g., the City of Llano). Many small towns often struggle to proactively reduce future flood risk due to limited resources such as staffing and funding.

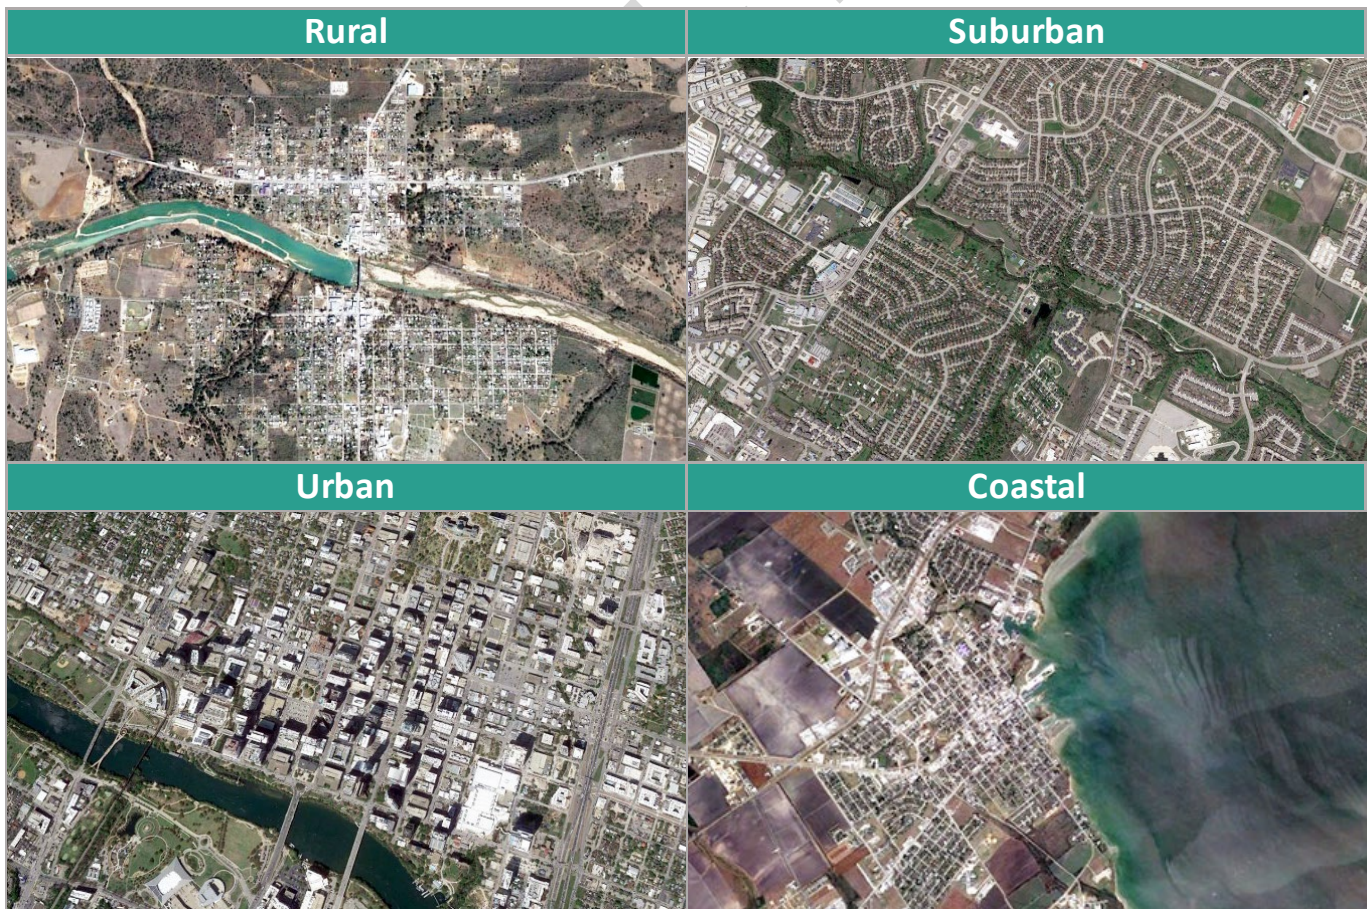

In the rapidly intensifying suburban areas (e.g., on the outer fringe of the Austin Metropolitan Area), new growth develops over open lands and natural areas by increasing impervious surfaces while simultaneously reducing the land’s natural ability to absorb flood water. In these areas, increased efforts are needed on flood mitigation to prevent future populations from being placed in areas of increased

flood risk. However, since many development decisions are made using data on current site-specific conditions, they often do not consider that changes in land use, in the aggregate, exacerbate flood problems over time.

In urbanized areas, like downtown Austin and some of the original core areas of our larger cities, past development decisions have already placed citizens in harm’s way, particularly for more vulnerable populations. As changes in rainfall intensity and duration continue to worsen over time, these areas will simultaneously be dealing with efforts to mitigate future problems stemming from new development/redevelopment and adapting to intensifying impacts in previously developed areas. Since these areas are also the employment centers and hubs of commerce, disruptions stemming from flood events can cause significant impacts on local and regional economies.

The coastal areas in the region also require special attention. While the character of development in these areas may exhibit rural, suburban, or urban characteristics, they must simultaneously prepare for the intensifying impacts of both riverine and coastal flooding. They are located at the most downstream point of the Lower Colorado-Lavaca River basin and thus eventually receive the flood waters from all upstream flood events. They are also increasingly subject to intensifying coastal-related impacts like coastal flooding stemming from hurricanes and rising sea levels.

Figure 1.4 Character of Development and Flood Risk

Urbanized Areas

Of the 376 local communities in the Lower Colorado-Lavaca Region (as detailed in the TWDB Water User Group Data), there are eight communities with a population greater than 10,000 and three communities with a population greater than 30,000 (Table 1.2). The cities with the largest population in the northern, central, and southern portions of the basin include Brownwood (Brown County; 39,761) in the northern portion of the region, Austin (Travis County; 1,298,624) in the central portion of the region, and Victoria (Victoria County; 93,857) in the southern portion of the region.

*Indicates cities with a population greater than 30,000

Source: 2021 Regional Water Plan - Population Projections for 2020-2070

Existing and Projected Growth by Hydraulic Unit Code (HUC)-8

The current growth patterns are generally projected to continue over the next 30 years, with greater concentrations of the population being aggregated in urbanized areas and the possible continuation of a declining population in more rural areas. The analysis for this section was undertaken using the Water User Groups and HUC-8 watershed population projections provided to each region by the TWDB from the State Water Plan. From 2020 to 2050, the number of communities with populations over 10,000 is projected to increase from eight to 17.

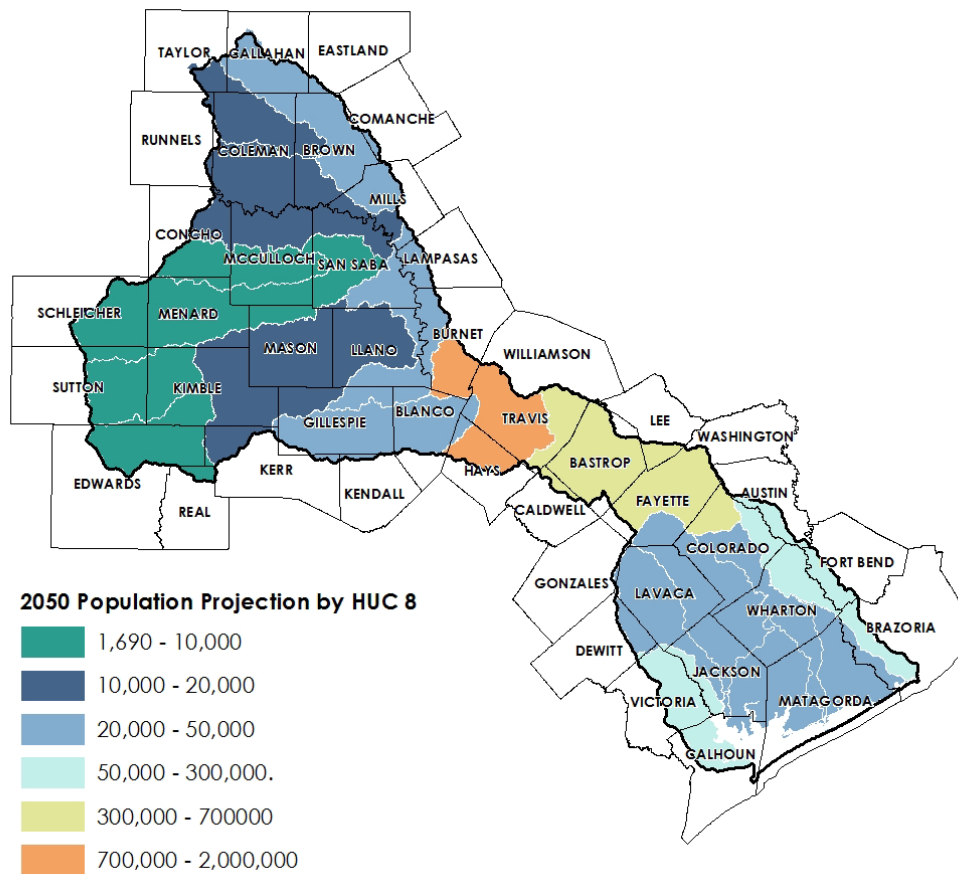

The Austin-Travis Lakes HUC-8 watershed is projected to have the largest concentration of population (almost 1.4 million) by 2050 (State Water Plan). Image Source: Shutterstock.

By 2050, the Austin-Travis Lakes HUC-8 is projected to contain almost 1.8 million people. This is an increase of 34 percent from 2020 to 2050. Within the region, the second largest population is projected to be in the Lower Colorado-Cummins HUC-8, which will contain 567,772 people by 2050, an increase of 43 percent over the next 30 years (Figure 1.3).

In this timeframe, the Lower Colorado-Lavaca Region is projected to have a population increase of almost 33 percent (Table 1.3). See Figure 1.5 2050 HUC-8 Watershed Population Projections illustrating the projected growth in population in each HUC-8 watershed.

Figure 1.5 2050 HUC-8 Watershed Population Projections

Source: TWDB Population Estimates

Similar to today’s general population distribution, the largest concentration of population is expected to remain in the Austin Metropolitan Area, where by 2050, the total population just within the City of Austin is projected to exceed 1.5 million people. As set out in Figure 1.5, the watersheds with the greatest projected population growth in terms of percentage of increase include Lower-Colorado-Cummins (43 percent or +245,000 people), San Bernard (40 percent or +35,000 people), and Austin-Travis Lakes (34 percent or +619,000 people). This information shows that the region’s greatest population increase between 2020 and 2050 will continue to be in cities next to or adjacent to the metropolitan areas with the largest and most dense pockets of population.

Table 1.3 Existing and Projected Population by HUC-8 Watershed

HUC-8 Name	HUC-8 ID	2020 Population	2050 Population	Population Change %	2020 Density (People/Square Mile)

2019 Daytime and Nighttime Population Grids

When considering flood risk, preparedness, and mitigation, it is important to know the extent of human exposure to flooding at various times. This is critically important in that population density, and thus exposure, changes in geographic location and intensity throughout the day and night. The TWDB provided a LandScan™ geodatabase to help identify and prepare for these changing exposures.

As seen in *Figure 1.6 2019 Daytime/Nighttime Population Grids*, the LandScan™ geodatabase shows that Travis County contains the greatest daytime population in 2019 out of all counties in the region (Map 1.6A). This indicates a large number of individuals either working or spending daytime hours in or around the City of Austin. In 2019, Bastrop County and Hays County contained the second and third largest number of individuals during daytime hours.

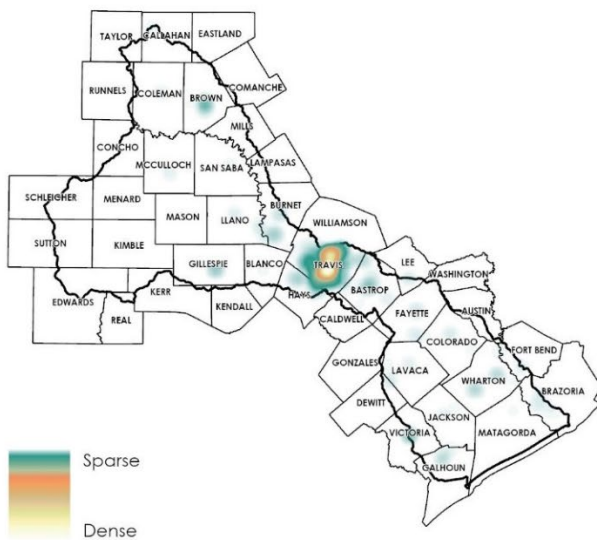

Map 1.6B shows that a larger concentration of individuals spent the nighttime hours in Travis County in 2019 compared to other counties in the region. During the day, individuals who spend time in Austin disperse to the surrounding suburbs of Pflugerville, Manor, and Del Valle at night.

LandScan™ Population Projection Geodatabase

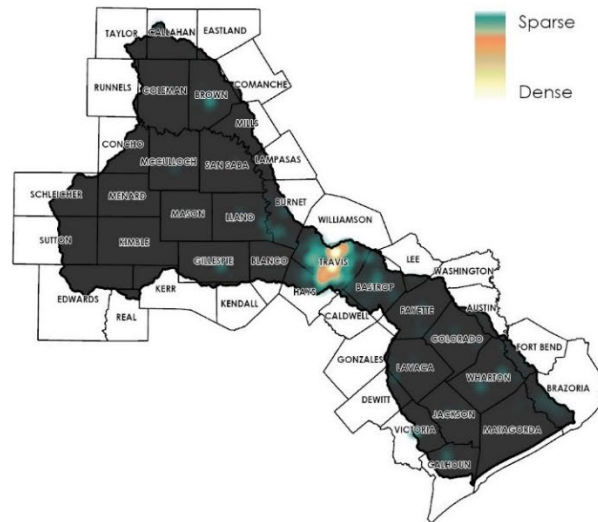

Oak Ridge National Laboratory's (ORNL's) LandScan™ is a community standard for understanding population distribution. It uses geographic information system (GIS) mapping and remote sensing to disaggregate census counts within a specific area to develop day and night population estimates. Since individual population distribution models can account for the differences in spatial data accessibility, quality, scale, and precision as well as the differences in cultural settlement practices, information gathered can determine which properties and structures as well as the number for residents that could be affected by future flood risk.

Figure 1.6 2019 Daytime/Nighttime Population Grids

Map 1.6A: Daytime

Map 1.6B: Nighttime

Source: 2019 LandScan™ USA for Day/Night Populations

2019 Daytime and Nighttime Building Populations

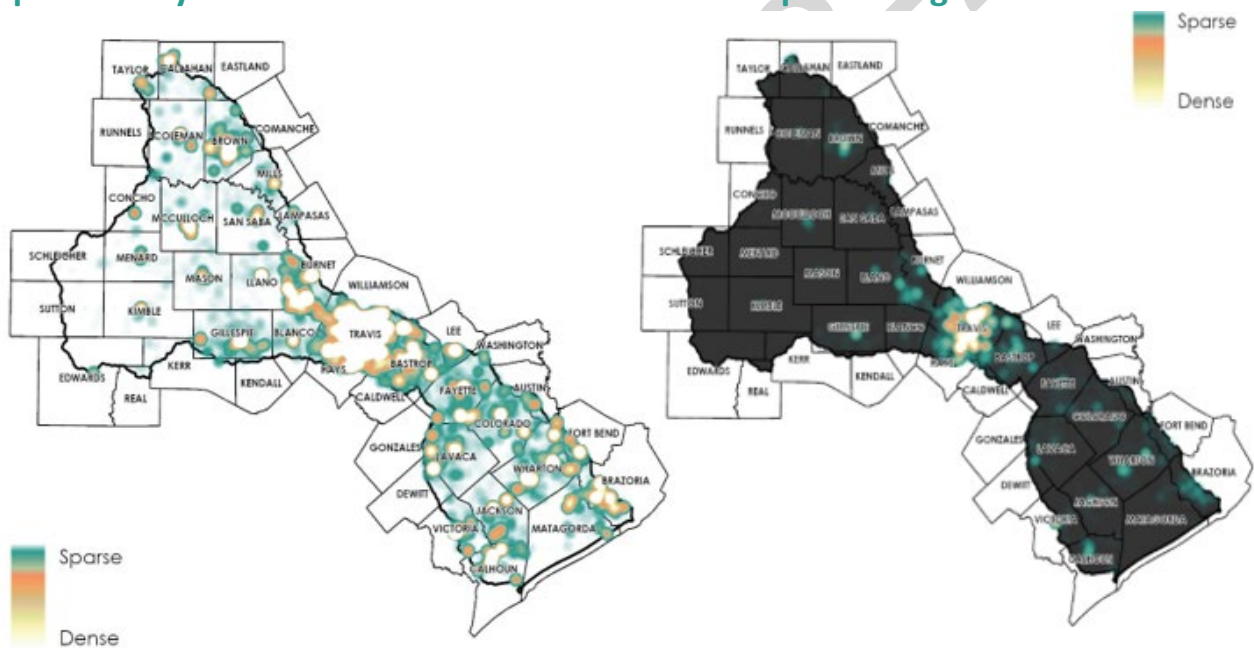

The TWDB also provided building footprints (e.g., homes, structures, etc.) with LandScan™ geodatabase populations to indicate how many people occupy the buildings during the daytime and nighttime hours. As indicated in *Figure 1.7 2019 Daytime/Nighttime Building Populations*, the yellow areas illustrate the highest concentrations of the population. The brownish to orange areas show the next level of population concentration.

As is evident on *Maps 1.7A and 1.7B (Figure 1.7)* the general population aggregates into higher intensity employment centers during the daytime working hours, with the largest concentration occurring in the Austin Metropolitan Area. During nighttime hours, the general population disperses to lower-intensity residential areas. Although the Austin Metropolitan Area still has the greatest concentration of nighttime population, it is more dispersed than during daytime hours.

Economic Activity

To better understand the economic risk the region faces from flood events, this section summarizes the most significant industries by three factors:

1. Number of establishments
2. Annual payroll
3. Total annual revenue

Data from the 2017 five-year American Community Survey (*U.S. Census Bureau*) was utilized to identify the most predominant industries within the basin. Industries were divided following the North American Industry Classification System (NAICS), which classifies all business establishments to facilitate the publication of statistical data related to the United States economy. Identifying the dominant industries in each category highlights the economic sectors with the highest potential for economic impact in the event of a flood.

Number of Establishments

The Lower Colorado-Lavaca Flood Planning Region contains important industries such as accommodation and food services; professional, scientific, and technical services; and retail trade, which contribute to the region's gross domestic product and support for the local and state economies. Based on the 2017 Economic Survey, the total value of sales or revenue generated by firms and businesses in the region amounts to over \$325 billion, constituting approximately 13 percent of the total sales/revenue generated by all firms and businesses in Texas. The main industry in the basin, by the number of establishments (i.e., the number of firms or businesses), is professional, scientific, and technical services at 67 percent. The retail trade industry makes up an additional 32 percent and the accommodation and food service industry is only one percent.

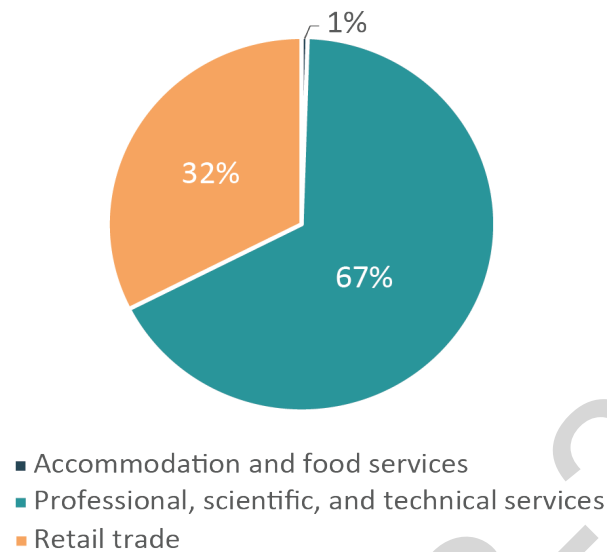

Figure 1.8 Establishment Percentages for Major Industries shows that the professional, scientific, and technical services sector employs approximately 137,884 employees, followed by the retail trade sector with approximately 487,909 employees. The industry sector employing the third-largest number of employees is accommodation and food services, with approximately 178,263 employees.

Annual Payroll

The total annual payroll in the Lower Colorado-Lavaca basin is \$58,301,823,000. *Figure 1.9 Major Industries by Payroll* shows that manufacturing is the largest industry by payroll in the region (28 percent), followed by transportation and warehousing (27 percent). Professional, scientific, and technical services and health care and social assistance represent the next largest share of all industries by payroll.

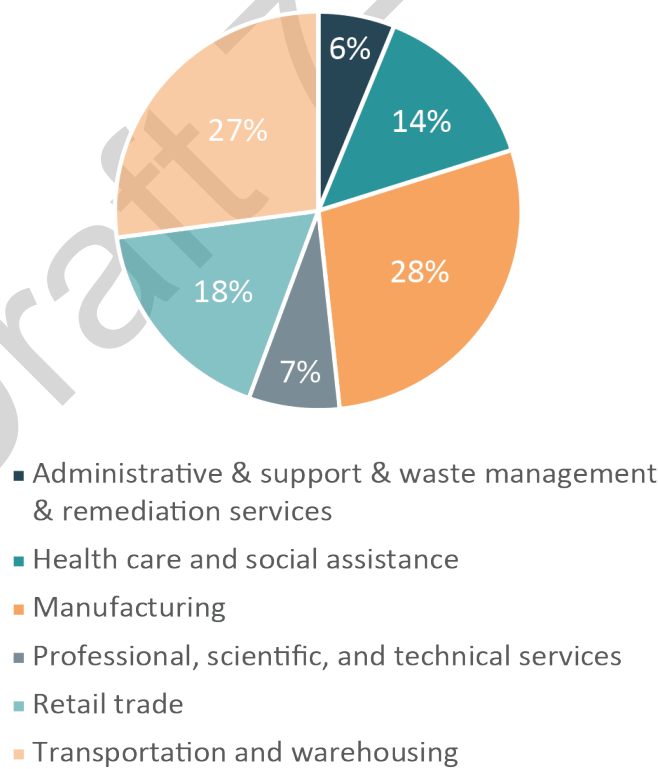

Regarding the share of payroll for the entire basin, professional, scientific, and technical services have an annual payroll of \$12,357,878,000, followed by health care and social assistance at \$8,497,817,000, and manufacturing at \$6,218,365,000.

Figure 1.8 Establishment Percentages for Major Industries

Figure 1.9 Major Industries by Payroll

Source: U.S. Census Bureau, 2017 Economic Census - Summary Statistics Table EC1700BASIC, Dataset ECNBASIC2017

By mitigating the impact of flooding on businesses, communities can make their residents more economically resilient. One factor that will be considered in this plan is social vulnerability, as measured by the Social Vulnerability Index, which accounts for the loss of income as one of the greatest predictors of future vulnerability for individuals and communities. The Social Vulnerability Index uses 15 different census variables to help identify communities that may need support before, during, and after a disaster. A severe flood event that affected income streams in these areas would heavily impact those vulnerable populations.

Total Annual Revenue

Of the three economic activity measures, the total revenue by industry may provide the most useful insight into a potential economic disruption of a major flood event by indicating the sectors most likely to be exposed to this risk, as it serves as a good indicator of which industries have the greatest economic impact. Inside the region, Travis County produces the largest commercial activity and most revenue, at \$163.7 billion, which also has the greatest number of firms or businesses (26,318) (Table 1.4). Its main industry sector is wholesale trade. Fort Bend County has the second greatest number of total firms and revenue, producing over \$45.9 billion, of which almost \$10 billion is in the retail trade industry. Brazoria County, in the southeast portion of the region and bordering Fort Bend County, produces the third-highest revenue, at \$37.1 billion, of which \$24 billion is produced in the manufacturing industry sector. The western side of rural Fort Bend County and Brazoria County are in the Lower Colorado basin and the greater economic activity is in the Lower Brazos Basin. The eastern sides of each of these counties are within the Houston Metropolitan Area. Table 1.4 Top Four Counties by Total Revenue, Firms, and Employees lists the four counties producing the most sales and revenue in the region. Travis and Fort Bend Counties also have the greatest number of firms and businesses, and their main industry sectors employ between 28,190 and 87,164 employees.

Table 1.4 Top Four Counties by Total Revenue, Firms, and Employees

County	Total Revenue (in Billions)	Total Number of Firms and Businesses	Total Number of Employees	Dominant Industry Sector
Travis	163.7	26,318	540,055	Wholesale Trade
Fort Bend*	45.9	15,663	213,164	Wholesale Trade
Brazoria*	37.1	5,304	91,045	Manufacturing
Hays*	10.2	3,066	51,798	Retail Trade

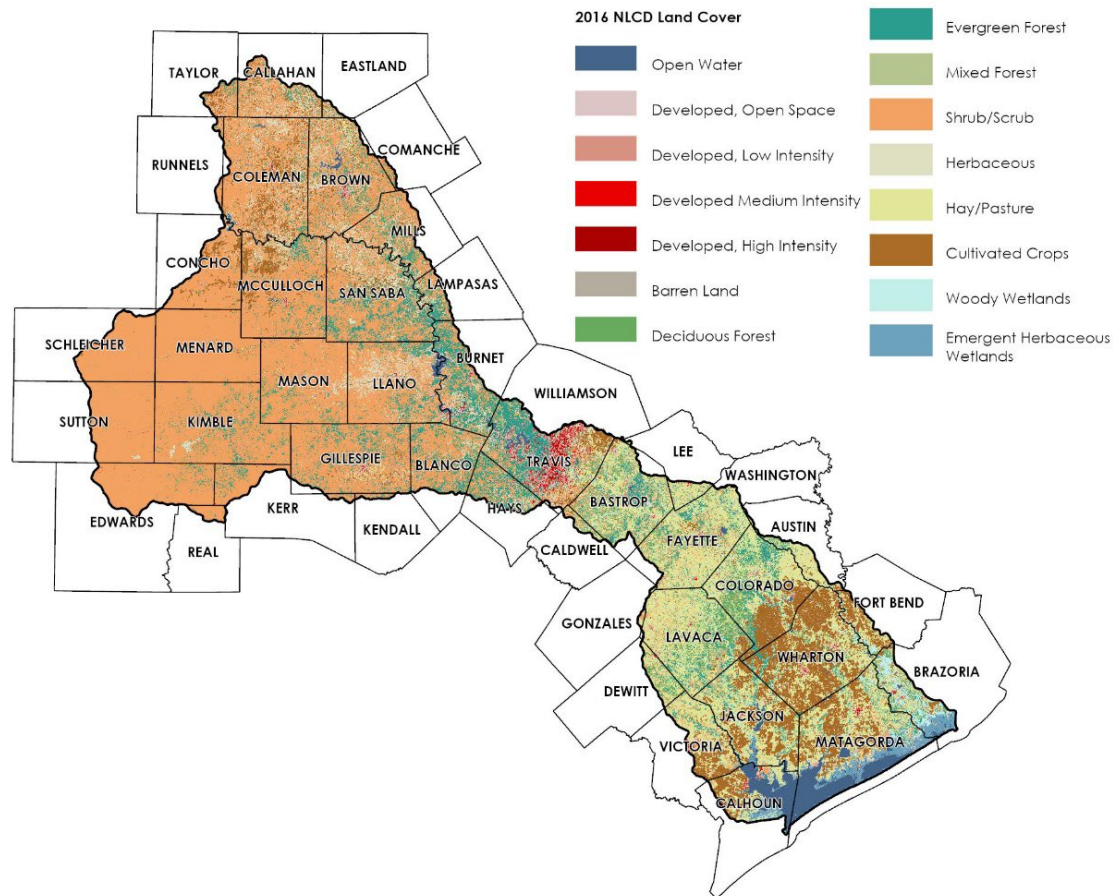

* Indicating counties partially in the region

Source: U.S. Census (Economic Census Summary Table, 2017, By County)

Land Cover and Use

As shown in *Figure 1.10 Land Cover*, the most prevalent land cover in the region is shrub/scrub at around 46 percent. It is the predominant land cover for much of the northern portion of the Lower Colorado-Lavaca basin. In the central portion of the region, the most developed area, only about 1.5 percent is developed at a low, medium, or high intensity. In these areas, however, increased impervious surfaces made up of materials that water cannot penetrate (e.g., roadways, rooftops, and parking) generally increase the potential for flood risk. However, the underlying geology of the Texas Hill Country is already fairly impervious bedrock such that increased development has less of an impact. Over time, the rapid development that is currently occurring in the Austin Metropolitan Area will continue to increase the amount of impervious surfaces throughout Travis County. Hay/pasture and deciduous, evergreen, or mixed forest make up around 14 percent of the region and are predominantly located within the southern portion of the basin.

Figure 1.10 Land Cover

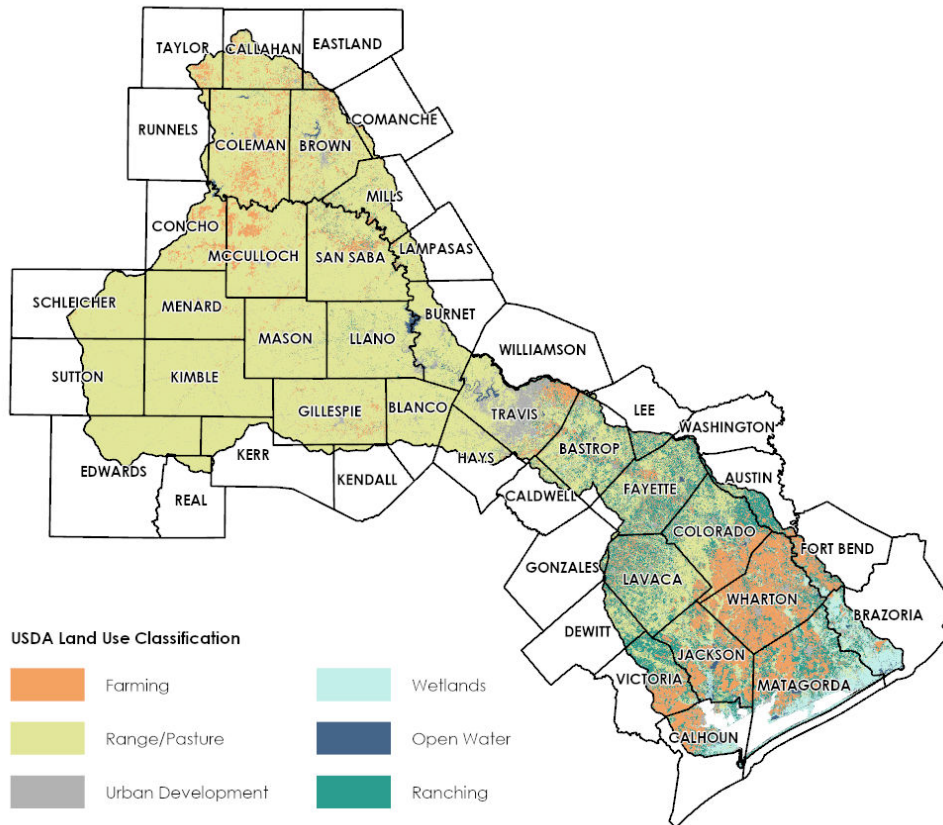

Source: United States Geological Survey (USGS) National Land Cover Database 2016 (USGS, 2016)

According to the United States Department of Agriculture (USDA) Land Cover data, the rural areas in the Lower Colorado-Lavaca basin contribute to the region's economy through farming, ranching, and range/pasture. *Figure 1.11 Land Use* displays the United States Department of Agriculture (USDA) land

use classifications in the region. The largest land use classification is range/pasture at 64 percent of the region, followed by farming at 12 percent. Only a small portion of the region falls under the urban development land use classification and is comprised of only 4 percent.

Figure 1.11 Land Use

Source: United States Department of Agriculture, National Agriculture Statistics Service

The Edwards Plateau Ecoregion in Gillespie, Llano, Mason, Menard, and Kimble Counties in the northern part of the basin is home to the Texas Hill Country. The largest concentration of urban development is located in the Austin Metropolitan Area. In the basin's southern part, farmland is the main use of working lands. As the Colorado River descends south toward Matagorda Bay, it provides a water source for farming in Wharton County. In Colorado, Lavaca, and Fayette counties, ranching and range-land are the predominant uses. Large landholdings in these counties could also be reflected in socioeconomic data, where census tracts in these rural areas have a very high median income.

Agricultural and Ranching Activity

The Colorado River is one of the main rivers which traverse the Lower Colorado-Lavaca Region. It passes through extremely productive agricultural areas with a rich farming and ranching heritage. Although fewer individuals are exposed to flood hazards in these areas than compared to more urbanized areas, the impact of flooding on agriculture, ranching, and range/pasture can be severe and have serious local and regional economic consequences.

Flooding on farm and ranchland, like this flood near La Grange in Fayette County, can have significant impacts on local and regional economies. Source: Shutterstock.

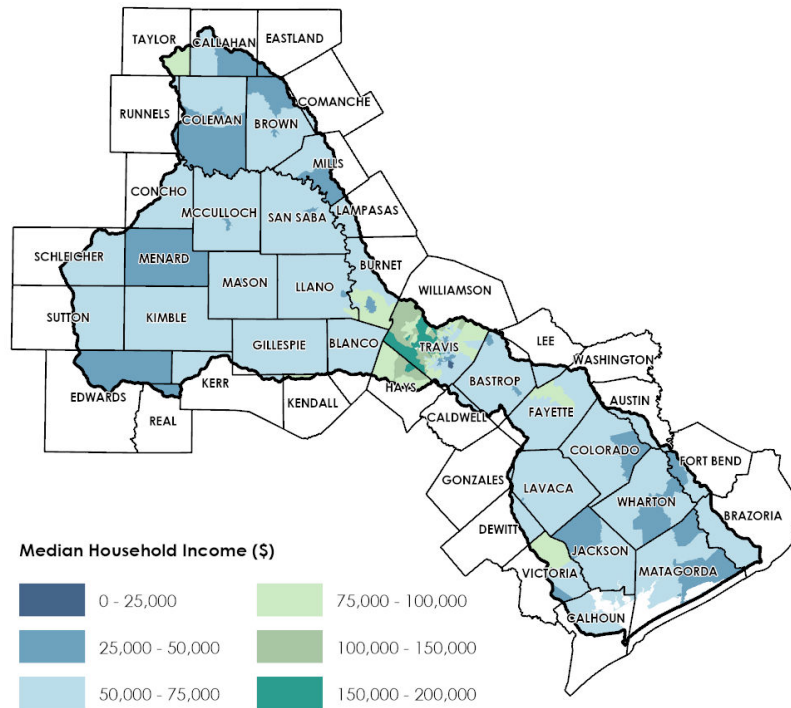

Floods can delay the planting season as flooding immerses the fields, making them impassable for heavy equipment. This can lead to decreased crop size, lower yields, and reduced profits. When floods occur as crops grow in the fields, they can destroy an entire season's work and investment. Floods at harvest time can make it impossible for farmers to harvest mature crops and get them to market. Livestock could drown in floodwaters if they do not have access to a higher elevation where they can escape. Even if the livestock is safe, the damage could occur to barns and other buildings, and cleanup of muck and debris can affect their feeding grounds. Forestry or orchard operations can lose trees to fast-moving waters and erosion, instantaneously wiping out years of growth.

Economic Status of Population

Median household incomes can be affected by many factors, including education levels, employment opportunities, and location. The median household income measure divides the data into two halves and compares income levels across the basin.

Figure 1.12 Median Household Income displays the median household income in the region and *Table 1.5 Median Household Income Per County* displays the average median household income of all counties in the region. The highest median household income in this area is between \$85,580 and \$100,795 in Travis and Hays Counties. The lowest median household income is in the northwest and southeast areas of the region. The counties in the southeast portion of the region are disproportionately affected by the projected increased rainfall from NOAA Atlas 14.

Social Vulnerability Analysis

When anticipating the likely extent of damages to a community from catastrophic floods, it is important to consider “exposure” based on the geographic location of people and property. It is also important to consider the “vulnerability” of populations to flooding impacts. Vulnerability is the measure of the capacity to weather, resist, or recover from the impacts of a hazard in the long term as well as the short term. “Vulnerability depends upon many factors such as land use, extent and type of construction, contents and use, the nature of populations (mobility, age, health), and warning of an impending hazardous event and willingness and ability to take responsive actions” (Wright, 2007).

Disasters affect different people or groups in different ways, ranging from their ability to leave an area in harm’s way, to the possibility of damage to their homes and properties, to their capacity to gather the financial resources required to recover and rebuild after a storm. These factors are known as Social Vulnerability, or an individual’s or group’s “capacity to anticipate, cope with, resist and recover from the impacts of a natural hazard” based on their relative vulnerability. Determining communities with high social vulnerability in the Lower Colorado-Lavaca Flood Planning Region is important for both flood planning and mitigation. Communities with high social vulnerability are at increased risk of experiencing loss of life and property in a flood event. Federal agencies like the Centers for Disease Control and Prevention (CDC), Federal Emergency Management Agency (FEMA), and the United States Department of Housing and Urban Development (HUD) use the Social Vulnerability Index (SVI) to help communities during and after human-made and natural disasters.

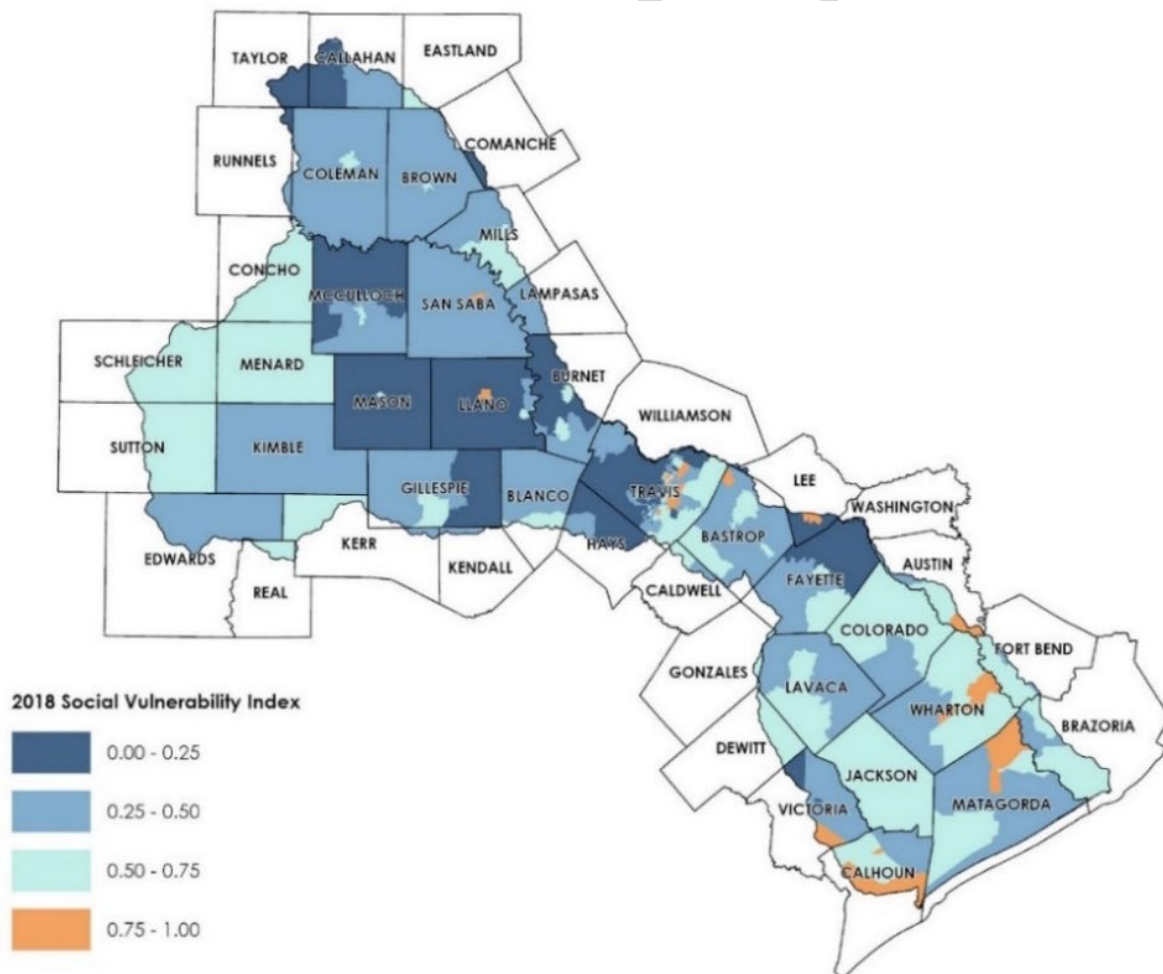

Measures of vulnerability are on a scale of zero to one, with one being the highest level of vulnerability, and are used to map social vulnerability in the region at various scales. The index focuses on 15 demographic indicators (Jaimie Hicks Masterson, 2014). These include:

- Below poverty
- Unemployed
- Low Income
- No vehicle
- No high school diploma
- Aged 65 or older
- Aged 17 or younger
- Civilian with a disability
- Single-parent households
- Minority status
- Multi-unit
- Mobile homes
- Crowding
- Group quarters
- Language barriers

The presence of several factors above in a population, or even an individual household, has proven to be a consistent indicator of the lasting impact of a disaster. Decreasing social vulnerability can reduce both human suffering and financial damage. The SVI variables are used to help local officials identify communities that could require support before, during, or after disasters. This plan will consider the location of highly socially vulnerable populations with respect to future needs for protecting critical facilities and investing in flood mitigation projects.

Figure 1.13 Social Vulnerability Index (SVI) shows the counties with the highest SVI in the region. They include Matagorda County (Bay City), Calhoun County (Seadrift and Port O’Connor), and Wharton County (El Campo, Wharton, and Hungerford). Identifying the locations of social vulnerability clusters helps inform where changes to flood mitigation programs, policies, and interventions can help lessen their social vulnerability. Interventions to reduce flood impacts in socially vulnerable areas can occur at all phases of a disaster, including pre-disaster mitigation and preparedness, response, and recovery. Focusing just on reducing the physical exposure to flooding may fail to adequately protect those most vulnerable and have the least ability to prepare, respond, and recover from flood impacts.

Flood-Prone Areas and Flood Risks to Life and Property

A strong baseline understanding of exposure and vulnerability is needed for Texas to better manage flood risk to mitigate the loss of life and property from flooding. This is a critical step in decreasing the vulnerability of the Lower Colorado-Lavaca Region's people and places to future flooding.

Currently, a patchwork quilt of plans, regulations, and infrastructure protects Texans from flood exposure. This planning mainly occurs at a local level, with varying standards that make it very difficult to quantify risk throughout the region. However, like in most areas, flood prevention efforts in the region largely focus on implementing the FEMA National Flood Insurance Program (NFIP) requirements. FEMA's NFIP is a federal program that provides flood insurance to property owners, renters, and businesses to recover faster after a flood. While it does help reduce the socioeconomic impact of floods, its primary focus is not on flood prevention.

FEMA's NFIP uses Flood Insurance Rate Maps (FIRMs) to identify special flood hazard areas, help mortgage lenders determine insurance requirements, and communities develop strategies for reducing risk. The average age of the region's FIRMs is 10 years, with an average date of January 1, 2014. Currently (2021), there are 6,564 flood insurance policies in the region and 5,103 flood insurance claims with a total value of \$142.9 million. This is good news, as it improves their prospects for economic recovery in the event of a major flood. It is also bad news in that many communities are using maps that are decades old and may only tell part of the story, including accounting for flooding that occurs outside floodplains. They may not reflect changing patterns of development and frequently fail to identify flood risks associated with changes in the topography, environment, and increasing climate change.

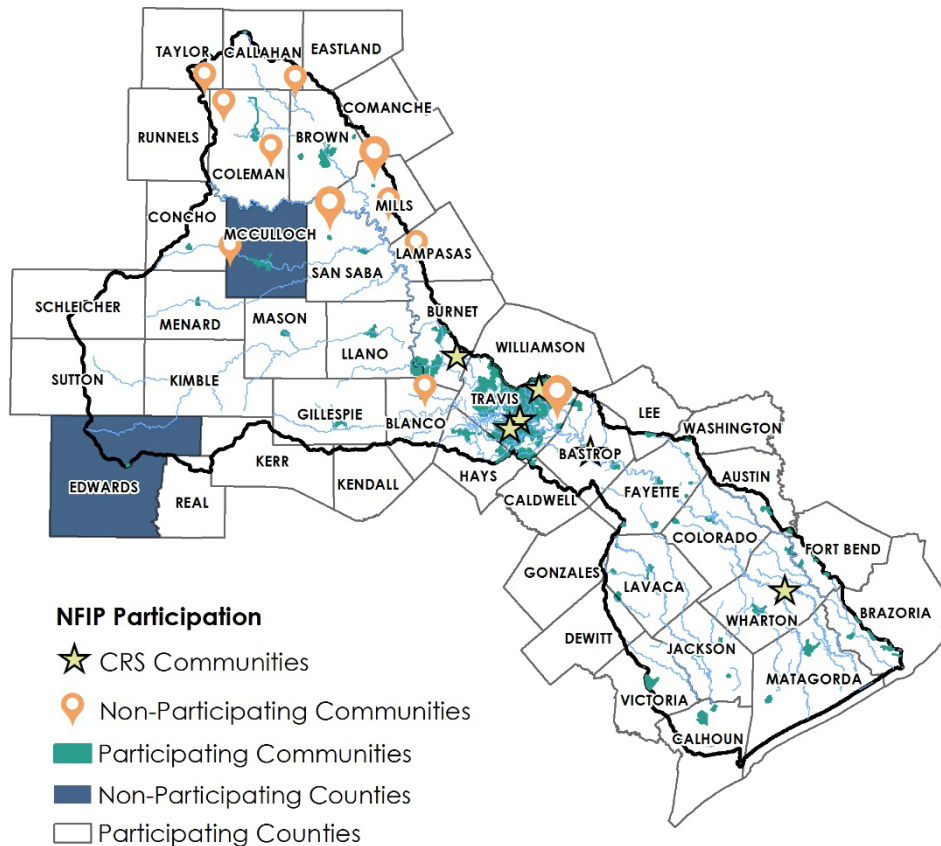

Figure 1.14 National Flood Insurance Program Participation displays the region's communities participating in the NFIP. The map also shows the communities participating in the Community Rating System (CRS), which is a voluntary incentive program that identifies and encourages community floodplain management practices that exceed the minimum requirements of the NFIP. The CRS uses a class rating system similar to the Fire Insurance Services Office rating that helps identify how prepared a community is for fires. Similarly, the CRS helps identify how prepared a community is for floods.

Under the CRS, flood insurance rate premiums are discounted to reward community actions that meet the three goals of the CRS, including:

1. Reduce flood damage to insurable property
2. Strengthen and support the insurance aspects of the NFIP
3. Encourage a comprehensive approach to floodplain management (FEMA)

Only four municipalities are CRS participants in the Lower Colorado-Lavaca Region, including Austin, Pflugerville, Sunset Valley, and Wharton. CRS participating counties include Bastrop and Burnet Counties. All counties except Edwards and McCulloch Counties participate in the NFIP and all cities except Cross Plains, Goldthwaite, Lawn, Melvin, Mullin, Novice, Richland Springs, Round Mountain, Santa Anna, and Webberville are NFIP participants.

Figure 1.14 National Flood Insurance Program Participation

Source: FEMA National Flood Insurance Program Community Rating System (FEMA, NFIP, CRS) 2020

Identification of Flood-Prone Areas

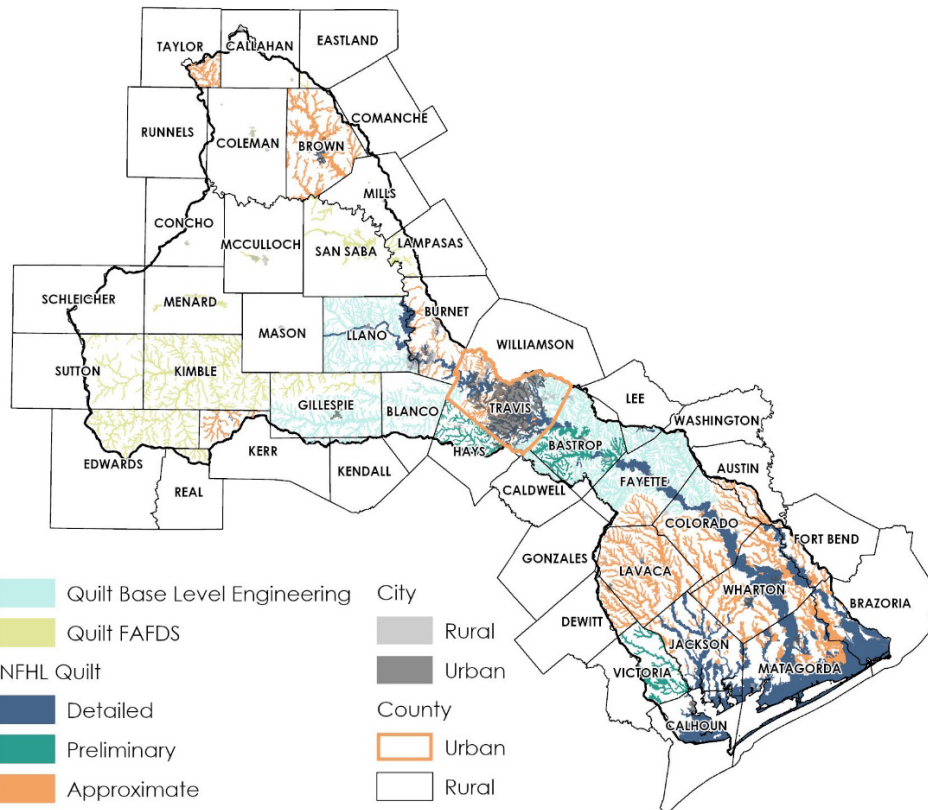

According to current NFIP mapping, 10 percent of the total area in the region is within the 1 percent to 0.2 percent annual chance event (ACE) which can otherwise be described as facing between a 1 percent or/and 0.2 percent annual risk of loss. This does not provide a comprehensive accounting for all flood risks, as not all floodplains within the Lower Colorado-Lavaca Region have been modeled and mapped. While developing a comprehensive flood risk model of the region is beyond the scope of this planning effort, the TWDB floodplain quilt used in this plan is “sewn” together from various sources of data (e.g., National Flood Hazard Layer, Base Level Engineering, Local Studies, etc.) to provide comprehensive coverage of all known existing statewide flood hazard information.

In the absence of a unified flood map that applies throughout the region, the subsequent chapters of this assessment will piece together an intricate floodplain quilt, combining numerous data layers from FEMA, including effective maps, preliminary maps, base level elevation maps, data from other federal agencies, local and regional studies, and commercial data from Fathom. *Task 2: Flood Risk Analysis* provides additional details regarding these datasets.

Types of Flood Risk

Figure 1.15 Initial Floodplain Quilt versus Urban Areas shows the initial floodplain quilt information provided by the TWDB that serves as the Lower Colorado-Lavaca Region’s starting point, providing an approximation of region-wide flood risk currently available data.

Figure 1.15 Initial Floodplain Quilt versus Urban Areas

Source: TWDB Floodplain Quilt with TxDOT Urban Areas

The TWDB provided this data to provide the RFPs with a common starting point for their compilation of flood risk data in their regions. In subsequent chapters, this “quilt” will be confirmed, updated, and otherwise enhanced as appropriate to prepare a larger flood risk assessment (TWDB, 2021). When complete, this regional floodplain quilt will identify information gaps and more accurately approximate the distribution of flood risk across the region.

A general definition of flood is an overflow of land not normally covered by water and which has three general characteristics: 1) the inundation is temporary; 2) the land is adjacent to and inundated by overflow from a river, stream, or creek, or an ocean, sea, lake or other body of standing water; and 3) damages or destruction of property and loss of life can occur. Adverse effects include damages to buildings, bridges, and other man-made structures, potential loss of life, inundation of roadways, backwater in sewers or local drainage channels, creation of unsanitary conditions, streambank erosion and deposition of materials during recession, rise of ground water coincident with the increased

streamflow and other related problems. Due to the varying ecoregions and topography, the Lower Colorado-Lavaca Region experiences multiple types of flood risk, as described below.

- **Local (Urban) Floods:** Local floodplains are those flood-prone areas located outside of mapped effective FEMA flood zones, designated Special Flood Hazard Areas (SFHA), shown on FIRMs. Typically, urban communities identify local flooding as roadways, subsurface infrastructure, and areas conveyed upstream of storm drainage inlets.

Nationwide, these flood zones have several names, including “urban floodplains,” “residual floodplains,” and “local floodplains,” and are in developed or developing areas. Due to local drainage floodplains not being mapped on FIRMs, some communities have begun taking steps to better define and understand local flooding risks in their community by using strategies such as local knowledge, historical events, and approximate or detailed local flood modeling studies, drainage master planning, local neighborhood analysis, and large scale two-dimensional (2D) hydraulic modeling. Although not regulated by the FEMA criteria, these areas often represent a significant portion of known flood hazards within the city, accounting for an inordinate proportion of federal flood insurance claims.

- **Riverine Floods:** Riverine flooding is very common in the Lower Colorado-Lavaca Region. Many communities have been developed near rivers or streams to take advantage of the aesthetic and recreational benefits they provide. Riverine flooding occurs when excessive rainfall over an extended period causes a river, stream, or creek to exceed its channel capacity. Overbank flooding occurs when the water rises and overflows over the edges of a river or stream. This is the most common and can occur in any size channel, from small creeks to huge rivers. One specific form of flooding is the “Flash Flood,” which is characterized by an intense, high-velocity torrent of water that occurs in an existing river channel with little or no warning time. Flash floods are very dangerous and destructive because of the force of the water and the debris that is often swept up in the flow. Floods on larger river basins are destructive and dangerous but normally develop over a long period and allow for significant warning and preparation (such as evacuating flood-prone areas).

The severity of a riverine flood is determined by the amount of precipitation in an area, how long it takes for precipitation to accumulate, previous saturation of local soils, and the terrain in the watershed or catchment area. In flatter areas, floodwater rises slower, is generally shallow, and may remain longer. In hilly areas, floods can occur within minutes after a heavy rain/flash flood event. To determine the probability of river flooding, hydrologic and hydraulic models consider past precipitation, forecasted precipitation, current river levels, the effectiveness of flood control structures, and other related factors. Riverine flooding depicted on the community’s FIRM is intended to show the extent of riverine floodplains in a community. Thus, updating outdated FIRMs, modeling areas that have never been mapped, and performing detailed studies where there are currently no detailed studies would improve the definition of riverine flood risk.

- Coastal Floods:** Coastal surge flooding occurs in the southern portion of the region along the Gulf Coast. It is typically the result of extreme tidal conditions caused by severe weather. Storm surge, produced when high winds from hurricanes and other storms push water onshore, is the leading cause of coastal flooding and often the greatest threat associated with a tropical storm. In this type of flood, water overwhelms low-lying land and often causes devastating loss of life and property.

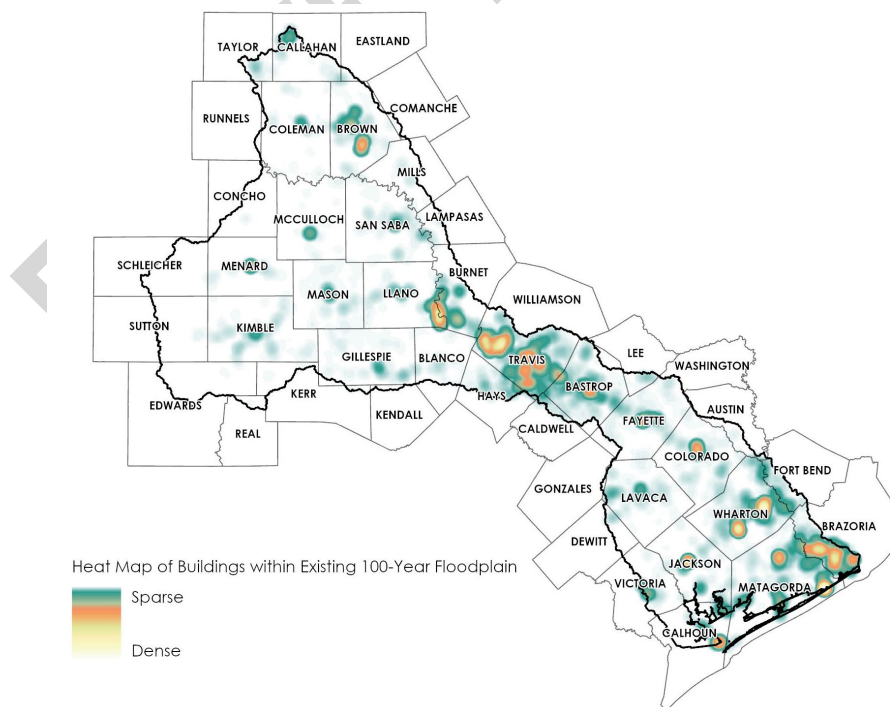

The severity of a coastal flood is determined by several factors, including the strength, size, speed, and direction of the storm. The onshore and offshore topography also plays an important role. To determine the probability and magnitude of a storm surge, coastal flood models consider this information in addition to data from historical storms that have affected the area, as well as the density of nearby development.

- Structural Failure Floods:** Structural failure flooding rarely occurs in Texas. Failure of flood infrastructure (e.g., dams, levees, etc.) may occur when excessive rainfall over an extended period causes an uncontrolled release of floodwaters. The severity of structural failure flooding is determined by the extent of failure, downstream topography, and downstream hazards (e.g., people, properties, roadways, etc.).

Flood Exposure

An initial assessment of exposure to flood risk can be observed utilizing building footprints in relation to the region-wide existing condition 1 percent ACE floodplain.

Figure 1.16 Structures Heat Map

Source: Building Heat map derived from existing condition floodplain in relation to the TWDB building footprints.

Impact to structures after flooding in the Central Texas Region. Source: Shutterstock.

The least amount of structures are found in the northwest portion of the region, while the southeast portion from Llano County to the Gulf of Mexico contains a much larger number of structures in multiple communities. *Figure 1.16 Structures Heat Map* shows the number of structures by density. The City of Austin in Travis County contains the densest and largest number of structures in the entire region. Brazoria, Matagorda, and Wharton Counties also contain a significant number of structures at risk of flooding.

Changes in Rainfall Data

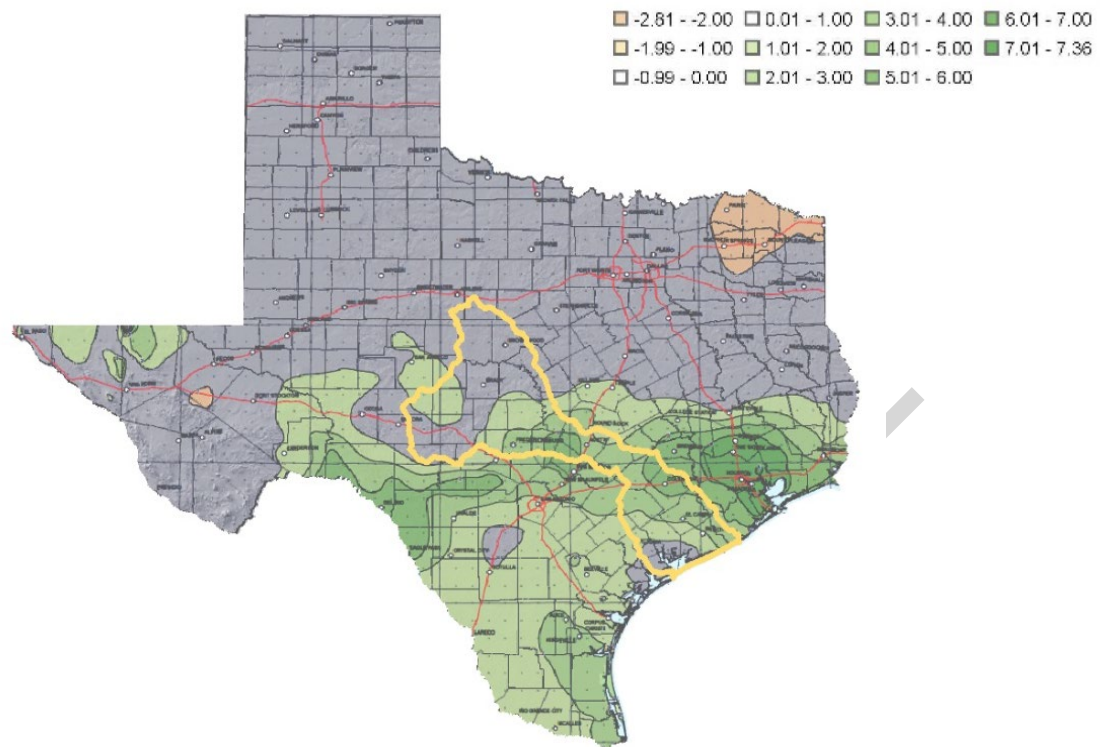

On September 27, 2018, the National Oceanic and Atmospheric Administration (NOAA) published new precipitation-frequency values for Texas.

This new publication, *NOAA Atlas 14 Precipitation-Frequency Atlas of the United States, Volume 11 Version 2.0: Texas*, is a reassessment of historical rainfall data up to 2017, adding an additional 20 years of record to the United States Geological Survey (USGS) publications (*Perica et al. 2018*).

Major events during this time period include Tropical Storm Hermine in 2010, the Blanco River Memorial Day Flood in 2015, and Hurricane Harvey in 2017.

Rainfall data is commonly used to predict flood risk and as an input to analyze and design flood protection/mitigation infrastructure such as bridges, culverts, channels, storm drainage systems, detention facilities, and others. The Atlas 14 publication indicates that the 1 percent annual chance, 24-hour rain event may be greater than what was previously considered in many areas. The greatest rainfall changes occurred in Central Texas and along the Texas coast. Outlined in yellow in *Figure 1.17 Atlas 14 Rainfall increase from USGS Rainfall* is the Lower Colorado-Lavaca Region. The green areas in the map indicate areas where rainfall depth increased compared to the USGS publications. There are minimal changes in the upper portion of the basin, with the greatest increases (approximately 3 inches) in the Austin Metropolitan Area. While three inches may not seem significant, it dramatically expanded the extent of the 100-year floodplain in Austin.

Key Historical Flood Events

The frequency and impact of historical events in the Lower Colorado-Lavaca Region can be evaluated using a variety of datasets such as previous occurrence disaster declarations, major rainfall events, stream gage data, insurance claims, NOAA reported losses, and others.

Disaster Declarations and Major Events

According to FEMA Disaster Declarations Summary data, there have been 50 federally declared major disasters and six emergency declarations in the region between 1953 and March 2020. Over 25 percent of the disaster declarations and 50 percent of the emergency declarations have occurred within the region since 2008, indicating that a flooding-related disaster occurs in the region approximately every year. *Figure 1.18 Historical Property Losses* displays the total property losses from flooding events between 2011 and 2021 (NOAA Storm Event Database). Within the Lower Colorado-Lavaca Region, the counties with the most property losses in the last 10 years were Fort Bend County and Brazoria County, encompassing over 80 percent of the total losses. In the heart of Flash Flood Alley, Travis County and Hays County have experienced the most flood-related fatalities.

Figure 1.18 Historical Property Losses

Source: NOAA Storm Event Database

The cycle of catastrophic disasters in the Colorado-Lavaca Region varies each year. For many years, no recorded disaster has reached either the level of a national Disaster Declaration or an Emergency Declaration. Frequently, however, when one disaster occurs, it is followed by one or more catastrophic events in the same year. Since 1953, there have been six Emergency Declarations and 50 Disaster Declarations within the Colorado-Lavaca Basin regions. Some of the most significant events in the Lower Colorado-Lavaca Region include:

- October 2018 Flood Events:** In October 2018, the Highland Lakes watershed had historic flooding with two flood events along the Llano River and Lakes LBJ and Marble Falls. The Lower Colorado River Authority (LCRA) opened eight floodgates at Buchanan Dam, 10 floodgates at Wirtz Dam, and four floodgates at Mansfield Dam. Lake Travis rose to 704.39 feet mean sea level, 23 feet above its full elevation.
- 2017 Hurricane Harvey Flooding Response:** Employees across LCRA worked together to address the challenges from Hurricane Harvey. LCRA activated the Emergency Operations Center and representatives from numerous departments shared updates and coordinated ways to solve challenges from the hurricane. In some areas, the Lower Colorado River rose to levels not seen in over a century.
- 2015 Wimberley Flood:** On May 26, 2015, a widespread eight to 10 inches of rain fell across Bandera, Kerr, Kendall, Blanco, and far west Comal and Hays Counties, with totals up to 10 to 13 inches in southern Blanco County. Most of the rain occurred in only a few hours. The Blanco

River at Wimberley rose 36 feet in four hours, with a maximum rise of 20 feet in one hour. Twelve people were killed and over 1,000 homes were destroyed or damaged, with public damages estimated at \$33 million.

- **2015 Memorial Day Austin Flood:** The Wimberley rains moved into downtown Austin dropping three inches on the already saturated ground within three hours. Shoal Creek, which drains west of Austin, rose to almost the 1981 elevation. The House Park High School football stadium and nearby areas flooded, necessitating swift-water rescues of residents.
- **2015 Halloween Austin Flood:** Back on Halloween in 2013, heavy rains flooded homes along Onion Creek in southeast Travis County. In 2015, a second storm hit almost the exact location with the same results. This time hundreds of homes were flooded and four people were killed. Onion Creek rose to 41 feet, surpassing the record of 38 feet set in 1869 and 1921.
- **2010 Tropical Storm Hermine:** Hermine made landfall in northeast Mexico and headed north through Texas. From September 6-9, 2010, rains from the Tropical Storm were four to six inches in Victoria and over 10 inches in Austin, with 15.62 inches recorded in Georgetown. A large band of 10-15 inches of rain fell from Austin to Waco.
- **2007 A "Rain Bomb":** In June 2007, around 19 inches of rain fell over the Marble Falls area in 12 hours. Most of the rain and runoff went into the Pedernales River and Lake Travis, which rose over 20 feet above its full elevation. The neighborhood of Graveyard Point, located far into the Lake Travis flood pool, was affected as the lake rose to 701.51 feet above mean sea level—its fifth-highest all-time elevation.
- **1991 The "Christmas Flood":** The "Christmas Flood" of 1991 rose Lake Travis to its record high elevation, creating flooding in the Lower Colorado River basin. This was the first flood of 10 years of substantial, reoccurring flooding that changed how LCRA responds to floods.
- **1981 Lavaca:** On August 31, 1981, Hallettsville was struck by a flood. Every business on the square received flood damage. At one time, the Square was submerged with 5.5 to 6.5 feet of water.
- **1981 Memorial Day Austin Flood:** On May 24, 1981, several hours of rain turned Shoal Creek into a raging torrent; 13 people drowned. This flood is credited with "waking Austin up to floods." Since then, the city has spent \$200 million to buy 450 homes, built flood walls and retention ponds, expand creek capacity, and improve storm drains.

1981 Lavaca Flood newspaper article. Source: Unknown.

1981 Shoal Creek flood near Lamar Boulevard. Source: Unknown.

- **1940 Hallettsville:** In the 1940 Hallettsville Flood, the Lavaca River rose to 41 feet which was 10 feet above any previous record. Several people were killed and several hundred thousand dollars in property were lost. A 4 inch rain occurred on a Saturday morning, followed by a downpour at night. A 10.5-inch rain fell, supplemented by a 16 inch rain in the Moulton section.
- **1936 LCRA'S First Major Test:** The Colorado River basin previously endured substantial floods in the 1930s, including a 1935 flood through downtown Austin. LCRA was still securing federal funding to build the Buchanan Dam when the June 1935 flood occurred. Floodwaters from over 50 inches of rain passed through the Buchanan Dam construction site. The substantial flooding on the Colorado River split Austin in half, leaving the bridge the only passable connection from north to south Austin. Flooding in July 1938 almost put LCRA out of business but exposed the need for LCRA to construct the Mansfield Dam to a higher elevation. An additional disastrous flood occurred in the basin in September 1936. Immense floodwaters from a record 25 inches of rain in July 1938 forced LCRA to open 22 of Buchanan Dam's 37 floodgates. LCRA added 78 feet to the height of Mansfield Dam and created a system of rainfall and river gauges—the forerunner of LCRA's modern electronic Hydromet system.

Past Causalities and Property Damage

The National Oceanic and Atmospheric (NOAA) storm events database includes a record of historic financial property and crop losses, injuries, and fatalities for each hazard since 1996. It should be noted that this database relies upon communities to provide estimates of loss and, therefore, may somewhat underestimate losses due to lack of data. Since the data provides a date, state, and county of impact, the data could be assessed to evaluate flood-related losses for the Lower Colorado-Lavaca Region. Table 1.6 displays historical losses per county for the last 10 years (2011-2021). The graphic below provides a spatial view of losses across the Lower Colorado-Lavaca Region.

Table 1.6 NOAA Storm Event Losses between 2011 and 2021 for Flood Related Hazards

Region	Property Losses	Crop Losses	Injuries	Fatalities
Austin County	\$2,420,000	\$50,000	-	1
Bastrop County	\$5,610,000	-	-	-
Blanco County	\$20,000,000	-	-	3
Brazoria County	\$2,000,556,000	\$100,000	-	-
Brown County	\$2,405,000	-	-	2

Region	Property Losses	Crop Losses	Injuries	Fatalities
Taylor County	\$394,000	-	-	-
Travis County	\$132,100,000	-	-	14
Victoria County	\$160,330,000	\$20,000,000	1	1
Wharton County	\$200,001,000	-	-	-
Lower Colorado-Lavaca Region Totals	\$12,238,267,000	\$40,318,000	4	50
Average Annual Loss (over the 10-year period)	\$1.2 billion	\$4 million	0.4	5

Crop Damage

The National Oceanic and Atmospheric (NOAA) storm events database was also used to summarize reported historical flood-related losses from the last 10 years. This database includes all storm events as provided by public submission to a National Weather Service representative. In the last 10 years, reported crop losses in the Lower Colorado-Lavaca Region totaled \$40 million.

Figure 1.19 Disaster Declarations with Crop Damages displays the total number of disaster declarations with crop damage between 2017 and 2020 per county. Within the Lower Colorado-Lavaca Region, the counties with the most declared disasters with crop damage were Colorado, Lee, and Wharton counties, with a total of four disaster declarations with crop damages in each county. During this time, the counties in the southeast and west have experienced more total crop disasters than the rest of the region.

Figure 1.19 Disaster Declarations with Crop Damages

Political Subdivisions with Flood-Related Authority

There are various regional political subdivisions with flood control authority, some with overlapping and/or joint regulatory responsibilities. In some instances, there may be competing interests and priorities even within the same area. State guidelines for "Flood Protection Planning for Watersheds" define political subdivisions with flood-related authority as cities, counties, districts, or authorities created under Article III, Section 52, or Article XVI, Section 59 of the Texas Constitution, any other political subdivision of the state, any interstate compact commission to which the state is a party, and any nonprofit water supply corporation created and operating under Chapter 67. Of the political subdivisions referred to above, the majority are municipal or county governments, both of which were given broad authority to set policy to mitigate flood risk.

The TWDB provided a list of 348 political subdivisions or entities that were thought to have some degree of flood-related authority in the region (*Table 1.7*). It is important to note that in the literal sense, "authority" could be any entity/agency that constructs, maintains, or otherwise touches a drainage system. In its purest sense, "authority" would only indicate entities with the authority to enact and enforce NFIP floodplain regulations (e.g., municipalities and counties). Throughout this report, distinctions are made to indicate whether the data is referencing all political entities or those with regulatory authority.

Representatives from each political subdivision were solicited to ensure receipt of the highest quality of information for each entity. Approximately 25 percent of the entities who received an invitation to participate in the flood planning process via the *Lower Colorado-Lavaca Region Data Collection Survey Tool and Interactive Webmap* provided at least some measure of response at varying levels of detail. Additional information and analysis will be further detailed in Chapter 3 and other chapters in this report.

Table 1.7 Political Subdivisions with Potential Flood-Related Authority

Entity Types	Number of Entities	NFIP Participants
Municipality	92	81
County	43	41
River Authority	3	N/A
Flood Control, WCIDs, Drainage Districts, Ports, Navigation Districts	70	N/A
Water Supply, Improvement, Utility Districts, MUDs, FWSDs, MWDs, SUDs, COGs	140	N/A

Source: TWDB Data Hub

In the Lower Colorado-Lavaca Region, 90 percent of eligible entities (municipalities and counties) participate in the NFIP. The Texas Water Code §16.315 requires NFIP participants to adopt a floodplain management ordinance and designate a floodplain administrator who will be responsible for

understanding and interpreting local floodplain management regulations and reviewing them for compliance with NFIP standards. Some of the rights and responsibilities granted under this authority include:

- applying for grants and financing to support mitigation activities
- guiding the development of future construction away from locations threatened by flood hazards
- setting land use standards to constrict the development of land which is exposed to flood damage and minimize damage caused by flood losses
- collecting reasonable fees to cover the cost of administering floodplain management activities
- using regional or watershed approaches to improve floodplain management
- cooperating with the state to assess the adequacy of local structural and non-structural mitigation activities

Summary of Existing Flood Plans and Regulations

The following tables summarize the entities' responses to questions about their existing regulatory environment and any measures they may have in place to increase resilience. The information in these tables is strictly based on responses to the data collection survey.

Table 1.8 summarizes the number of survey participants that have a particular regulatory or planning measure in place. These plans and regulations were divided into four categories: Drainage Criteria Manual/Design Manual, Land Use Regulations, Ordinances (Floodplain, Drainage, Stormwater, etc.), Unified Development Code (UDC), and/or Zoning Ordinance with map. Of the four types of regulations and plans, the largest number of respondents indicated that they had an active floodplain, drainage, and/or stormwater ordinance.

In general, these regulations and ordinances cumulatively:

- restrict and prohibit land uses that are dangerous
- control alteration of floodplains, channels, and natural protective barriers
- describe permitting and variance procedures for land use regulation in relation to flood prevention
- define the duties of the floodplain administrator
- specify subdivision and construction standards
- prescribe penalties for non-compliance to standards
- define overall rules and regulations for flood control and flood hazard reduction

Beyond regulations, *Table 1.8* identifies additional measures entities undertake to comprehensively promote resilience in flood-prone areas to mitigate the effects of flooding. As defined by FEMA, resilience aims to build a culture of preparedness through insurance, mitigation, continuity, preparedness programs, and grants. These measures include education and training, pre-planning, and early warning systems, among others.

Table 1.8 Types of Measures to Promote Resilience in Flood-Prone Areas

Measures to Promote Flood Resilience	Count
Acquisition of flood-prone properties	6
Flood readiness education and training	6
Flood response planning	11
Flood warning system	9
Higher Standards for floodplain management	14
Land use regulations that limit future flood risk	13
Participation in the Community Rating System (CRS)	5
Participation in the National Flood Insurance Program (NFIP)	24

Source: Lower Colorado-Lavaca Region Data Collection Tool and Interactive Webmap

Using plans and policies to reduce the exposure of people and properties to flood risk is a form of non-structural flood control. By encouraging or requiring communities to avoid developing in flood-prone areas or to take precautions such as increasing building elevation, preserving overflow areas through buffering, and avoiding sensitive natural areas such as wetlands, communities can prevent new development from being in harm’s way.

Floodplain Ordinances and Local and Regional Flood Plans

Floodplain ordinances dictate how development is to interact with or avoid a city’s floodplain. FEMA provides communities with flood hazard information based on floodplain management regulations. Floodplain ordinances are subject to the National Flood Insurance Program and ensure that communities and entities consider flood hazards when making land use and land management decisions. Ordinances may include maps with base flood elevations (BFE), any freeboard requirements, as well as criteria for land management and use. This information will be discussed in greater detail in Chapter 3.

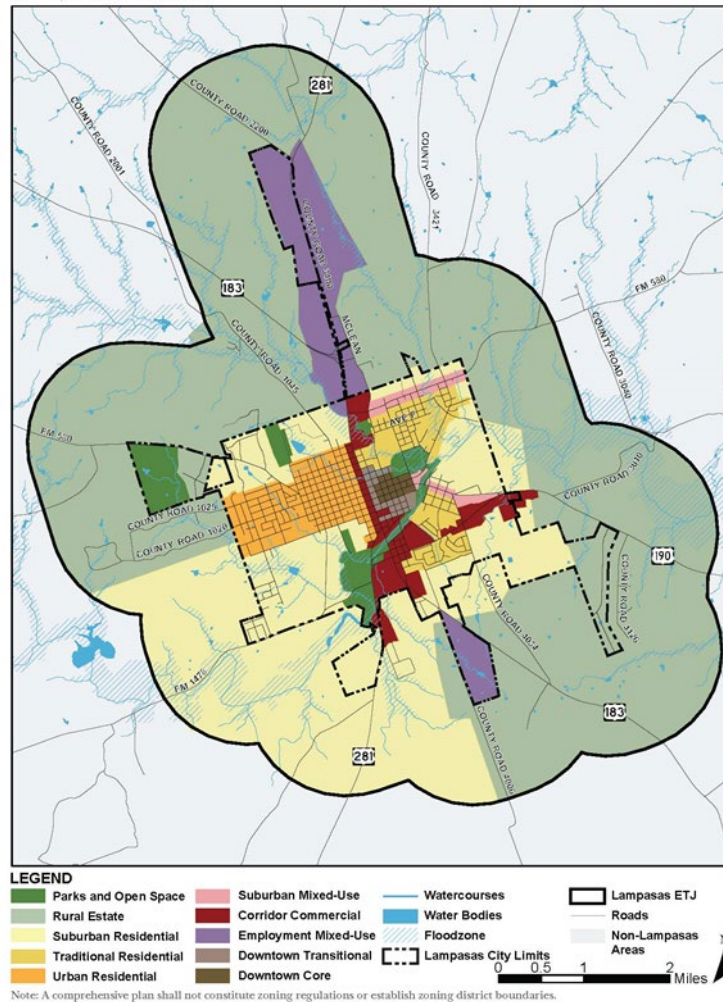

Comprehensive Plans and Future Land Use Plans

The comprehensive plan establishes policies and a program of action for a community's long-term growth and development. The future land use plan, sometimes called a FLU, provides a guide for future areas of growth and development, as well as areas that are to be conserved in their natural state. The comprehensive plan and its embodied FLU set the groundwork necessary to undertake quality decision-making for future growth and development. While many cities have future land use plans, the content of these plans varies widely in specificity. Irrespective, the existence of a future land use plan may mean that the City is likely taking a more detailed approach to the type and location of future development.

Comprehensive plans and their associated future land use plans also provide legal authority for zoning regulations in the State of Texas. They consider capital improvements necessary to support current and future populations and often consider social and environmental concerns the community wishes to address. To produce a comprehensive plan, communities undertake an extensive planning process that encourages discussion about topics such as risk from natural hazards and may include recommendations regarding the development location with respect to floodplains, the need for future drainage improvements, etc. (Figure 1.20). As many development decisions are made during the first step in the

development process, particularly during negotiated development proposals like planned unit developments (PUDs), it is critical for floodplains to be accounted for in these conversations.

Figure 1.20 City of Lampasas Future Land Use Plan

Delineating regulatory floodplains on the city’s future land use map in the comprehensive plans ensures that reducing future flood risk is part of the conversations of early development discussions, decisions, and approvals. Source: City of Lampasas

Land Use Regulations and Policies: Zoning and Subdivision

Zoning ordinances regulate how property owners can use their property and what types of uses are allowed within a certain area. It is one of the most important tools that communities use to regulate the form and function of current and future development. Within the zoning ordinance, communities may incorporate a variety of tools, which may include, among others:

- Stream buffers
- Setbacks from wetlands and other natural areas
- Conservation easements

Subdivision regulations get into a more focused regulation of the design and form of the building blocks of a city. They regulate platting processes, standards for the design and layout of streets and other types of infrastructure, the design and configuration of parcel boundaries, and standards for protecting natural resources and open space. While both cities and counties have subdivision ordinances, counties do not have zoning authority in Texas. As identified by the survey results, 16 jurisdictions indicated that they have land use regulations to manage existing or future flood risk as part of development. Eleven jurisdictions have indicated that they currently have unified development codes and/or zoning.

Drainage Criteria

Drainage criteria is created to set the minimum standards for design engineers to follow when preparing plans for construction within the jurisdictions in which they serve. These could be for municipalities or counties within the basin. The document covers standards pertaining to submissions, right of way/easements, hydrology, and hydraulics.

A storm drain system is defined as a network of open channels and underground pipes designed to capture and convey concentrated stormwater flows to a point beyond the developed property limits. Developers may sometimes oversee creating drainage infrastructure that will be continuous and synergistic with the existing storm drain system and will not prevent surrounding property owners from extracting economic benefits from their properties. As identified by the survey results, 12 jurisdictions have indicated that they currently have drainage criteria manuals/design manuals.

Drainage structures include such things as culverts to collect surface runoff and deliver it to underground stormwater conveyance systems.

Assessment - Existing Flood Infrastructure

Understanding the current context of the existing natural and structural flood infrastructure in the Lower Colorado-Lavaca Region is an important step in helping to identify the appropriate strategies and recommendations to reduce flood risk. Since the Lower Colorado watershed connects communities from Rocksprings in Edwards County to Matagorda County on the Matagorda Bay, flood infrastructure in this region benefits the community where it is located but could also have significant benefits for people and places downstream. When evaluating flood risk management infrastructure, this plan considers natural and manmade features that contribute to risk reduction. Examples are provided in *Table 1.9*.

Table 1.9 Examples of Natural and Structural Flood Infrastructure

Natural Features	Region Counts	Structural Features	Region Counts
Rivers, tributaries, functioning floodplains	1,897,093	Levees	24
Lakes, reservoirs, <i>playa lakes</i>	267	Dams that provide flood protection	696
Parks, preserves, natural areas	471	<i>Regional detention, retention ponds</i>	2,030
Wetlands and marshes	49,081	Local stormwater systems, including tunnels, canals	0
<i>Karst features, sinkholes</i>	7	Roadways, low water crossings	1,352
<i>Alluvial fans</i>	0	Sea walls, revetments	431
Coastal barriers, nourishment, dunes	81	<i>Tidal barriers, gates</i>	0

Note: Features shown above in italics have not been identified as major components of flood control systems in the Lower Colorado-Lavaca Region.

Flood infrastructure in the Colorado-Lavaca Region consists of an intricate network of natural areas and built features owned and managed by entities ranging from the public sector to individual property owners. Flood infrastructure may include non-structural measures, such as natural area preservation, buyout of repetitive flood loss properties, and flood warning systems, but also includes all major public infrastructure, such as regional detention. The TWDB provided numerous data sources to assist with identifying flood management infrastructure in the Flood Data Hub. The region’s database was populated with available information from the TWDB and many other state and federal datasets, as outlined in the following sections. Where overlap occurred, the data sources were reviewed and amended to only include a single inventory per location.

There were also several questions posed in the data collection survey that complement the information provided by existing data sources to generate a more comprehensive picture of how communities in the Lower Colorado-Lavaca Region protect themselves from flood risk.

Natural Features

As pasture and fields are replaced by urban development, soil permeability decreases. This makes land less efficient at slowing down rainwater and letting it percolate into the soil and recharge the aquifer. Instead, urban drainage infrastructure often collects rainwater and speeds it directly into a drainage channel and networks. This increases the runoff's speed and intensity, making flood water peak quicker and potentially higher.

Since 2017, the Texas Land Trends project by Texas A&M's Natural Resources Institute (NRI) found that the Colorado-Lavaca Region lost over 213,000 acres of working land (crops, grazing lands, timber, and wildlife management) to urban and suburban development. While the population increased by more than 50 percent in the region during that time, only 1 percent of the total acreage of the natural areas was replaced with structures, roads, and parking lots. These hard, frequently impervious surfaces increase the potential for runoff to burden waterbodies downstream. The acreage that did remain as open space grew increasingly fragmented (Texas A&M Natural Resources Institute, 2021).

As the trend toward urbanization and fragmentation continues, the entities within the region will need to take a more thoughtful approach to manage its natural infrastructure to continue to receive the benefits of open spaces, which the U.S. Army Corps of Engineers (USACE) addresses in its Engineering with Nature initiatives. This initiative aligns natural and engineering processes to efficiently and sustainably deliver economic, environmental, and social benefits through collaborative projects. Currently, state and federal-level governments are managing local, state, and National Parks and Wildlife Management Areas, like the Aransas National Wildlife Refuge, that form part of the region's natural infrastructure.

When left in their natural state, landscapes are very efficient at handling rainfall. As raindrops fall from the sky, they are captured by trees, shrubs, or grasses, slowing their passage to the area's waterways and allowing rain time to soak into the soil. Wetlands and woodlands are most efficient at recycling rainfall, as the branches and undergrowth intercept water before it even reaches the ground, thus minimizing overland flow to tributaries and the river. Pastureland performs this function effectively as well, whereas cropland may shed a greater degree of water so as not to inundate the fields. Similarly, parkland in urban areas designed for dual functions can achieve nearly the same rate of stormwater capture as lands in undeveloped areas (Marsh, 2010). For natural features to achieve maximum effectiveness at flood mitigation, they should form part of an interconnected network of open space consisting of natural areas and other green features that also protect ecosystem functions and contribute to clean air. This is sometimes known as green infrastructure, the practice of replicating natural processes to capture stormwater runoff (Low Impact Development Center). Even small changes in developed areas can significantly impact downstream flooding.

Natural areas can be managed to be even more efficient at these functions in a variety of settings, including:

- **Watershed or Landscape Scale:** Where natural areas are interconnected to provide opportunities for water to slow down, soak in, and overtop the banks of creeks and channels

when needed. These solutions often include multiple jurisdictions and restoration of natural habitat to achieve maximum effectiveness. These areas may be embodied within the river corridors and tributaries, which exist in many cities and towns across Texas. When combined with regional greenway trail and recreation systems, these areas provide multiple benefits beyond just the conveyance of rainwater.

- **Neighborhood Scale:** Solutions built into corridors or neighborhoods that better manage rain where it falls. Communities establish regulatory standards for development that guide the use of neighborhood-scale strategies. These also provide great opportunities for neighborhood recreational connections to the regional greenway system.
- **Coastal Solutions:** To protect against erosion and mitigate storm surges and tidally influenced flooding, nature-based solutions can be used to stabilize shorelines and restore wetlands. (FEMA, 2021)

Rivers, Tributaries, and Functioning Floodplains

The natural flood storage capacity of all streams and rivers and the adjacent floodplains contribute greatly to overall flood control and management. Surface water, floodplains, and other features of the landscape function as a single integrated natural system. Disrupting one of these elements can lead to effects throughout the watershed, increasing the risk of flooding to adjacent communities and working lands. Maintaining the floodplain in an undeveloped state provides rivers and streams with room to spread out and store floodwaters to reduce flood peaks and velocities. Even in urban areas, preservation of this integrated system of waterways and floodplains serves a valuable function, as even small floods resulting from a 20 percent ACE (5-year) and a 10 percent ACE (10-year) event can cause severe flood damage.

At over 800 miles long, the Colorado River is one of the longest rivers to start and end in the same state and is the major river in this region. It originates in the rural areas of the High Plains and meanders southeast through farms, rangeland, and forest on its way south to the Gulf of Mexico. It is a critical resource to the Texas economy, the environment, industry, and agriculture. It also affects many Texans in that it passes through many urban areas, including the region's most heavily populated urban area, Austin, before reaching the coast at Matagorda Bay.

Similar to the floodplain quilt, the region's streams were populated with available information from FEMA, USGS, TWDB, and local entities. It should be noted that the streams are compiled from the best available datasets; however, they generally do not align with the current topography. Along with statewide mapping, the TWDB is developing updated stream layers that can be integrated into the next planning cycle. As displayed in *Table 1.10 Floodplains by HUC-8 Watershed*, there are over **TBD** stream miles in the Lower Colorado-Lavaca Region.

Table 1.10 Floodplains by HUC-8 Watershed

Lakes, Reservoirs, Parks, and Preserves

Lakes, reservoirs, parks, and preserves serve as essential components of the ecosystem as they house a wide variety of local flora and fauna and physical features necessary for the region's continued ecological health. Additionally, these areas can also be essential components of water retention during flooding and severe rainfall events. These types of natural flood infrastructure are generally located in or close to floodplain areas throughout the basin, with higher concentrations located along or close to the major rivers and tributaries. Indeed, in many of the region's original core areas of the city (e.g., Austin, Lampasas, Llano, Marble Falls, and Wharton), these areas were often set aside for public parks and green spaces.

Table 1.11 Lakes, Reservoirs, Parks, and Preserves by HUC-8 Watershed details the acreage of each of these natural features and the total land area in the HUC-8 covered by these natural features. East Matagorda Bay 1 in the southern tip of the basin, Austin-Travis Lakes in the central portion of the region, and San Bernard in the southern end contain the greatest percentages of land area covered with lakes, reservoirs, parks, and preserves. Other HUC-8s in the planning region have one to two percent of the land area covered with lakes, reservoirs, parks, and preserves.

Table 1.11 Lakes, Reservoirs, Parks, and Preserves by HUC-8 Watershed

HUC-8 Name	Lakes, Reservoirs (acres)	Parks (acres)	Preserves (acres)	HUC-8 Totals (acres)	Percentage of HUC-8 Area (% of land)

Wetlands and Marshes

Wetlands and marshes are some of the most effective features of recycling water, minimizing the overland flow and reducing the need for other flooding infrastructure. A robust concentration of wetlands directly surrounds the Colorado River, with less-concentrated wetlands throughout the region. As the Colorado River heads southward towards the coast, the concentration of wetlands increases. This not only mitigates flooding coming from upstream areas but also flooding coming from the coast in the form of hurricanes and other tropical storms. According to the USGS National Wetlands Inventory, wetlands comprise approximately 275,000 acres within the basin, as displayed in *Table 1.12 Wetlands by HUC-8 Watershed*. This means that wetlands are one of the basin's largest types of natural infrastructure.

Table 1.12 Wetlands by HUC-8 Watershed

Natural Coastal Features

The National Coastal Zone Management Program is a voluntary partnership between NOAA and coastal states that was formed between states and the federal government following the passage of the Coastal Zone Management Act of 1972. In Texas, this program is managed by the Texas General Land Office (GLO) and implemented through the 2019 Coastal Resiliency Master Plan (CRMP). The dynamics of flooding in coastal areas differ from riverine flooding in that they are influenced by issues such as sea-level rise, land subsidence, tidal flooding, storm surge, and rainfall events. Mitigating coastal flooding is one of the primary objectives of CRMP, and proposed natural solutions include: incorporating green infrastructure into development, creating flood-resilient parks and recreational spaces, retaining and restoring open space, and maintaining/creating freshwater wetlands and coastal prairies.

The state is updating the 2019 CRMP and anticipates the release of a new plan in 2023 that will include a list of projects in each region that can be incorporated into future planning cycles (Texas General Land Office, 2019).

Coastal features in the region are located in the southeast portion of Calhoun County, Jackson County, Matagorda County, and Brazoria County. Natural features along the coasts that could reduce flood impacts include tidal marshes, sandy beaches, mangrove-covered areas, and many bays, estuaries, and lagoons.

Structural Flood Infrastructure

Although Texas communities use various measures to protect themselves from future flooding (e.g., flood control reservoirs, dams, levees, local storm drainage infrastructure, etc.), dams may provide the most significant structural mitigation to regionally reduce future flood risk. Dams in Texas serve many purposes, including flood risk mitigation, irrigation, water supply, fire protection, and creating waterbodies for recreation. About one in three of the state's dams are for flood risk mitigation and one in seven dams are for irrigation or water supply.

Dams

The U.S. Army Corps of Engineers (USACE) maintains a database of dams nationwide, totaling 7,324 in Texas. The Texas Commission on Environmental Quality (TCEQ) maintains a database of similar state-regulated Texas dams (i.e., dams above the size thresholds of Texas Administrative Code Title 30, Part 1, Chapter 299). Dams of unregulated size are deemed not to provide a safety risk to lives in the event of a breach. Finally, the Texas State Soil and Water Conservation Board (TSSCWCB) maintains a list of 2,041 earthen dams designed and constructed by the United States Department of Agriculture – Natural Resources Conservation Service (USDA-NRCS). These data sources were reviewed and amended to only include a single dam per location, ultimately identifying 696 dams in the region.

Dams can be owned and operated by various organizations and people, including state and local governments, public and private agencies, and private citizens. Because of the diverse nature of ownership, the capacity of dams and the frequency of inspection may also vary widely. Although reasons for building dams may include water storage for human consumption, agricultural use, power generation, industrial use, and recreation, for the purposes of this report, the analyses will focus on how dams are used as part of flood control.

Levees

Levees are man-made structures that provide flood protection. Over one million Texans and \$127 billion of property are protected by levees. The Texas 2018 Levee Inventory Report lists 51 USACE levee systems in the State (2021 Texas Infrastructure Report Card, 2021). These USACE levees are frequently maintained and inspected to federal standards and provide a high standard of flood protection. Although not all are used for flood control purposes, failure of a single levee could have multiple consequences for property and human safety downstream.

According to the USACE National Levee Database, there are 24 levees in the Lower Colorado-Lavaca Region, with one managed by the USACE – Fort Worth District. The Texas Water Code §16.236 requires that the design be based on the 1 percent annual chance (100-year) event and provide three to four feet of freeboard in urbanized areas. The Water Code also outlines a review and approval process for the construction and improvement of levees following the filing of an application and a set of preliminary plans for the levee that includes sufficient engineering detail for evaluation. Applications must include the location and extent of the structure, the location of surrounding levees, reservoirs, dams, or other flood control structures which may be affected, and the location and ownership of all properties lying within any proposed protected area or others that may be affected by the project's alteration of the flood flow. The preliminary plans must demonstrate the proposed project's effects on existing flood

conditions. (Texas Commission on Environmental Quality, 2005). *Figure 1.21 Dams and Levees* and *Table 1.14 Dams and Levees by HUC-8 Watershed* provides the number of levees by HUC-8 watershed throughout the region.

Figure 1.21 Dams and Levees

Stormwater Management Systems

Stormwater management systems manage both the quantity and quality of the water that drains into the region’s rivers and tributaries. Although survey respondents provided limited information about their stormwater management systems, participants in the Texas Pollutant Discharge Elimination System (TPDES), which is managed by the TCEQ, are likely to have storm drainage infrastructure. Six cities in the region have drainage systems and are classified as Phase I Municipal Separate Storm Sewer Systems (MS4s): Austin, Pflugerville, Rollingwood, San Leanna, Sunset Valley, and West Lake Hills. An additional four cities in the region are classified as Phase II MS4s: Bee Cave, Buda, Hays, and Victoria.

Roadways

Low water crossings and at-risk roadway segments are utilized to assess existing condition risk, future condition risk, and potential mitigation benefits. The TWDB defines a low water crossing as a roadway crossing that is overtopped by the 1 percent ACE (100-year) or more frequent events. At-risk roadway segments are portions of the roadway that are inundated or impassable during flooding events that may impact emergency response or evacuation. The Lower Colorado-Lavaca Region’s database was initially populated with the TWDB-provided low water crossings and then refined using input from entities.

Structural Coastal Features

As stated previously, the GLO is in the process of updating the 2019 CRMP for Texas and anticipates the release of a new plan in 2023 (Texas General Land Office, 2019). The identified structural coastal projects will be incorporated in the next planning cycle. Structural coastal features along the region’s coast in Calhoun, Jackson, Matagorda, and Brazoria counties that help reduce flood impacts include sea walls, tidal dikes/barriers, revetments, and tidal gates.

Table 1.15 Roadways and Coastal Infrastructure

Condition and Functionality of Existing Flood Infrastructure

The TWDB-provided information and research on existing flood infrastructure provided little relevant information about the state of the region’s existing flood infrastructure, and no direct input was provided by survey respondents regarding infrastructure condition and functionality. The TWDB defines functional infrastructure as infrastructure that serves the current design level of service. A non-functional classification would indicate the infrastructure needs upgrades to meet a higher level of service. Similarly, the TWDB defines deficient infrastructure as being in a poor physical condition indicating the infrastructure needs replacement, restoration, or rehabilitation. To provide some level of assessment, the age of dams and levees was utilized where available to provide insight into the region’s existing flood infrastructure.

Throughout Texas, flood infrastructure is rapidly aging and in need of repair. In 2019, the Association of State Dam Safety Officials (ASDSO) estimated the cost to rehabilitate all non-federal dams in Texas at about \$5 billion. The TSSWCB estimates around \$2.1 billion is required to repair or rehabilitate dams

included in the Small Watershed Programs. Even though the minority of the dams in the region were constructed for flood control, the consequences of failure can still be severe, with the potential loss of life, agricultural resources, and property. Of the approximate 7,200 non-federal dams in Texas, about 25 percent could result in loss of life should they fail, and more than 3,200 Texas dams are exempt from dam safety requirements by state legislation.

The year of construction is available for the majority of the 696 dams in the Lower Colorado Lavaca Region, 77 percent of dams were constructed between 1950-1979. The 1960s were the most prolific period of dam construction in the region when over 41 percent were constructed. The percentage of dams constructed between 1950-1959 and 1970-1979 were roughly equal, at about 35 percent. With a typical life span of 50 years, over 50 percent of the dams in the region are reaching their life span.

Figure 1.22 Year of Dam Construction by HUC-8

Source: USACE National Inventory of Dams, TSSWCB Local Dams Listing

The most common reasons for dam failure include: overtopping by floods, foundation defects, piping and seepage (Texas Commission on Environmental Quality, 2006). Although entities provided little information about the nature of their dam infrastructure, the age of these structures indicates that many may be due for modernization, upgrades, maintenance, rehabilitation, or even retirement.

Failure of the Bastrop State Park Dam, which was originally constructed in 1913, during the 2015 Memorial Day flood event. Source. Texas Parks and Wildlife.

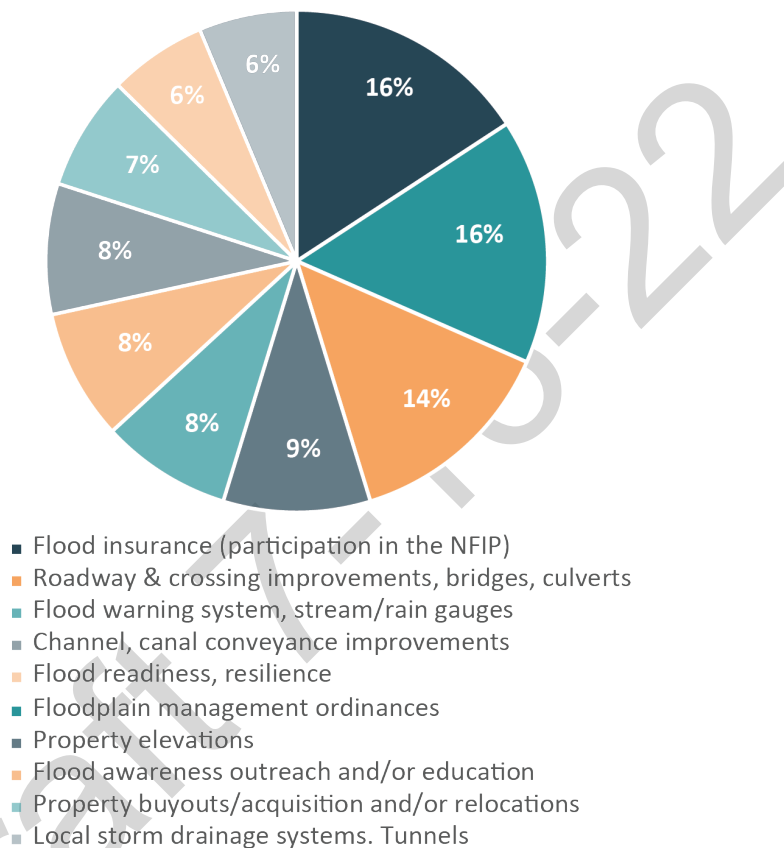

Condition-related data for the region's levees is mostly unknown, since most of the levees in the state are built, inspected, and/or maintained by local governing agencies who may not have the resources for routine assessment and performance tracking. Levees protect over one million Texans and \$127 billion worth of property. The Texas 2018 Levee Inventory Report lists 51 USACE levee systems with 291 miles protecting a population of 291,200 and 276 known non-USACE levee systems with 1,562 miles protecting a population of 707,700 statewide. Recent increases in the frequency and intensity of storms and hurricanes continue to test the capacity of the state's levees. Without a clearer picture of the state's levee infrastructure and concentrated funding to assist private owners, the vast majority of the state's levees will remain in the presumed deficient status (*2021 Texas Infrastructure Report Card, 2021*). Additionally, the American Society of Civil Engineers (ASCE) continues to give the state's levees a grade of D and emphasizes that the lack of a state levee safety program means that few entities may be conducting regular safety inspections and preparing public evacuation plans for affected communities.

Of the 109 miles of levees in the Lower Colorado-Lavaca Region, approximately 45 miles (41 percent) of them are identified as being accredited by the USACE. This also indicates that several of the region's levees may be due for modernization, upgrades, maintenance, or rehabilitation.

Action - Proposed/Ongoing Flood Mitigation

The data for this section is derived from two primary sources. The first source is the region’s data collection survey, which was supplemented by direct outreach and entity interviews. The second source is existing hazard mitigation plans in the Lower Colorado-Lavaca Region.

Figure 1.23 Top 10 Types of Proposed or Ongoing Flood Mitigation Projects

Source: Lower Colorado-Lavaca Region Data Collection Tool and Interactive Webmap

Current Flood Mitigation Activities

These proposed or ongoing flood mitigation projects are derived from the survey responses from completed by cities, counties, and additional entities throughout the basin.

Overall, 15 communities indicated in the survey that they planned to undertake a variety of Flood Mitigation Projects (FMPs) in the coming years (respondents could select more than one alternative).

The predominant types of projects being pursued are:

- Flood insurance (participation in the NFIP)
- Floodplain management ordinances
- Roadway and crossing improvements, bridges, culverts

Figure 1.23 represents the top 10 types of potential projects identified by survey respondents. Table 1.16 Proposed Projects by Type details the number of responses for all project types.

The largest number of respondents indicated continued participation in the NFIP flood insurance program and floodplain management ordinances (15 responses), followed by projects related to roadway and crossing improvements, bridges, culverts and channels, and canal conveyance improvements (eight responses).

Additionally, several respondents indicated projects related to flood mitigation, including property elevation (nine responses), flood awareness outreach and/or education (eight responses), and flood warning systems, stream/rain gauges (eight responses). While many of these project types are local in nature (e.g., property buyouts/acquisition and/or relocations), some may be better implemented regionally (e.g., flood warning).

Table 1.16 Proposed Projects by Type

Type of Projects	Count
Channel, canal conveyance improvements	8
Coastal groins, jetties, breakwaters	1
Flood awareness outreach and/or education	8
Flood insurance (participation in the NFIP)	15
Flood readiness, resilience	6
Flood warning system, stream/rain gauges	8
Floodplain management ordinances	15
Levees, flood walls	2
Local storm drainage systems. Tunnels	6
Nature-based projects	1
Property buyouts/acquisitions and/or relocations	7
Property demolition/reconstruction	4
Property elevations	9
Property floodproofing and/or flood retrofits	1
Regional dams, reservoirs, detention, retention basins	4
Roadway and crossing improvements, bridges, culverts	13
Sea barriers, walls, revetments	1

It is important to note that there are gaps and limitations provided by this data set. Overall, it only represents a small number of the communities within the region and little data was provided on individual projects. It is also important to note that there may be a larger number of projects than displayed since entities submitted the categories of projects they were pursuing but not the number of projects within each category. Future funding sources for these projects include FEMA, GLO, Community Development Block Grant Program - Mitigation (CDBG-MIT), TWDB, Texas Division of Emergency Management (TDEM), as well as cities’ typical funding sources coming from their general fund, taxes, and other fees.

Structural Projects under Construction

In the survey, 20 respondents listed that some of their proposed infrastructure or flood mitigation projects were at or above a 30 percent level of design. However, responses regarding projects under construction were insufficient to provide additional details regarding these projects. Chapter 2 includes a more detailed assessment of projects under construction.

Nonstructural Flood Mitigation Projects being Implemented

Information provided in response to entity outreach was insufficient to answer this question completely. Chapter 2 includes more information regarding nonstructural flood mitigation projects being implemented.

Structural and Non-Structural Flood Mitigation Projects with Dedicated Funding and Year Complete Funding Sources

Information provided in response to entity outreach is insufficient to answer this question completely. However, several respondents to the survey who indicated that they did have projects at a 30 percent level of design also indicated that Stormwater Utility Fees, Bond Programs, Ad Valorem Tax, and the General Fund were anticipated to be their primary source of revenue to complete these improvements. In particular, the General Fund was the funding source most identified. Additionally, nine communities identified that they do not have a local funding source for their flood management activities. Non-local funding sources that the entities intend to pursue to complete these projects include:

- Hazard Mitigation Grant Program (HMGP) [FEMA/TDEM]
- Community Development Block Grant-Disaster Recovery (CDBG-DR) [HUD/GLO]
- Flood Mitigation Assistance [FEMA]
- Community Development Block Grant-Mitigation (CDBG-MIT) [HUD/GLO]
- Flood Protection Planning Grants [TWDB]

Potential Benefits of Planned Mitigation Projects

Although most communities did not provide detailed information about their intended projects, there does appear to be substantial awareness of the value of preparing for future flood events. Survey responses and a review of hazard mitigation plans indicate that substantial investment is being made in local drainage, roadway, and flood control infrastructure. Without greater detail regarding the scale, complexity, and location of these projects, it is difficult to quantify the benefit received. Still, it is anticipated that the inventory of this information will continue to grow in future planning cycles.
