Flood Management Evaluation Memorandum

TO:	Lauren Graber Lower Colorado River Authority P.O. Box 220 Austin, TX 78767	DATE:	May 5, 2023
FROM:	Jay Scanlon, PE, CFM Freese and Nichols, Inc. F-2144 10431 Morado Circle, Suite 200 Austin, TX 78759	PROJECT:	LCRA Contract No. 5809 Halff AVO 43796.001 FNI HAF21363
SUBJECT:	FME ID: 101000053 Project Sponsor: City of Fredericksburg Project Name: Creek Street at Barons Creek		UEROME W. SCANLON II 82077 55 ONAL ONAL

On September 15, 2022, the Lower Colorado-Lavaca Regional Flood Planning Group (RFPG) approved the evaluation of this Flood Management Evaluation (FME) to identify, evaluate and recommend additional potentially feasible Flood Mitigation Projects (FMP).

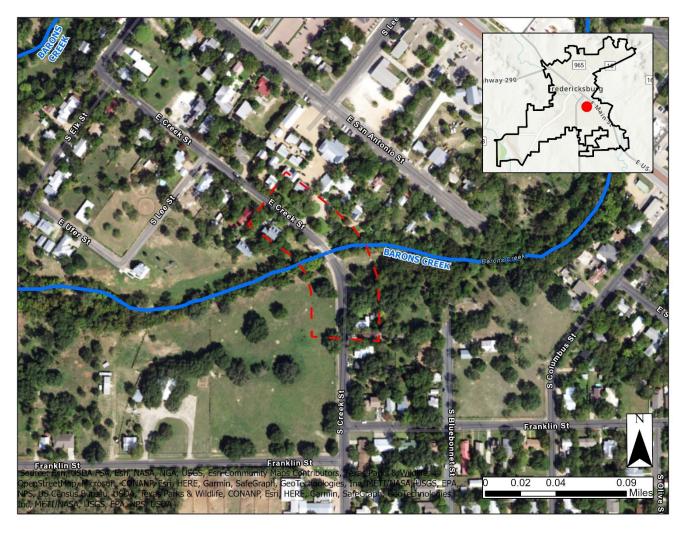

Introduction

The City's 2016 Drainage Master Plan (DMP) proposed the implementation of a Flood Early Warning System (FEWS) at Creek Street. This action is included in the adopted Regional Flood Plan as a recommended FMP that anticipated installation of the flood early warning system with no structural improvements to the roadway crossing. However, during the preparation of the Regional Flood Plan the City indicated they would prefer to look at structural solutions. Based on the Sponsor request, the Regional Flood Planning Group (RFPG) recommended inclusion in the Regional Flood Plan (RFP) as FME 101000053.

Mr. Garret Bonn, Assistant City Engineer, and Interim Director of Development Services, was contacted to confirm the City's support to have the RFPG perform this FME, as described herein, as part of the Task 12 effort. Mr. Bonn confirmed the general nature of the flood problem, is supportive of the study, and assisted with local information and will review the report deliverables.

This FME includes updating the FEMA flood hazard analysis and mapping with ATLAS 14 rainfall data and evaluation of mitigation alternatives. This FME also includes preliminary capital cost estimates, quantification of flood risk reduction benefits, benefit-cost analyses, adverse impacts evaluation, and a high-level evaluation of potential constraints including environmental permitting, utility relocations, right-of-way acquisition, and constructability issues in accordance with adopted FMP screening criteria.

Figure 1: Study Area Location

Modeling Analysis

The following sections provide an overview of the data, methodologies, hydrologic analysis, and hydraulic analysis used to identify the existing condition flood risk.

Data Collection

The sources of the key data collected and leveraged for analysis are listed below.

- Terrain Data: 2019 LiDAR (70cm), obtained from Texas Natural Resources Information System (TINRIS).
- Soils Data: 2022 Natural Resource Conservation Service (NRCS) Web Soil Survey.
- Land Use Data: 2019 National Land Cover Database (NLCD).
- Survey Data: Creek St Culvert survey data was provided by City of Fredericksburg.
- Hydraulic model: HEC-RAS 1D model for Barons Creek was obtained from Federal Emergency Management Agency (FEMA) Base Level Engineering (BLE) Tools and Resources website.
- FEMA effective model: obtained from the 2016 DMP study.
- Spot elevations (survey) provided by the City.

Hydrology

In the original HEC-RAS 1D BLE model, Regression Equation was applied to calculate the peak flows. There is no HEC-HMS model available for the entire BLE area. To update the hydraulic model with NOAA Atlas 14 rainfall, a HEC-RAS 2D Rain-on-Grid model was developed to generate peak flows for the HEC-RAS 1D BLE model.

- Modeling Software: HEC-RAS version 6.3.1
- Rainfall Data: NOAA Atlas 14, 24-hour duration (2-, 5-, 10-, 25-, 50-, 100-, and 500-year frequency storms).
- Loss Method: NRCS Curve Number loss rate method

Hydraulics

The HEC-RAS 1D BLE model was updated with Atlas 14 computed flows and utilized for hydraulic analysis. Because the 1D BLE model is a low-detail engineering approach to provide a baseline understanding of the flood hazards, no hydraulic structures are included in the model. Structure data from FEMA effective model in the vicinity of project area were added to the model (Lincoln St, Washington St, Creek St, Main St, and FM 1631).

- Modeling Software: HEC-RAS version 6.3.1, 1D steady-state simulation
- Hydrologic Data: see above
- Boundary Conditions: Downstream normal depth

Existing Condition Flood Risk

The existing structure on Creek Street over Barons Creek is a triple 8' x 7' concrete box culvert. The capacity of the culvert is approximately 1,005 cfs without overtopping the road. Peak water surface elevations for the Q2 through Q100 storm events are presented in **Table 1**.

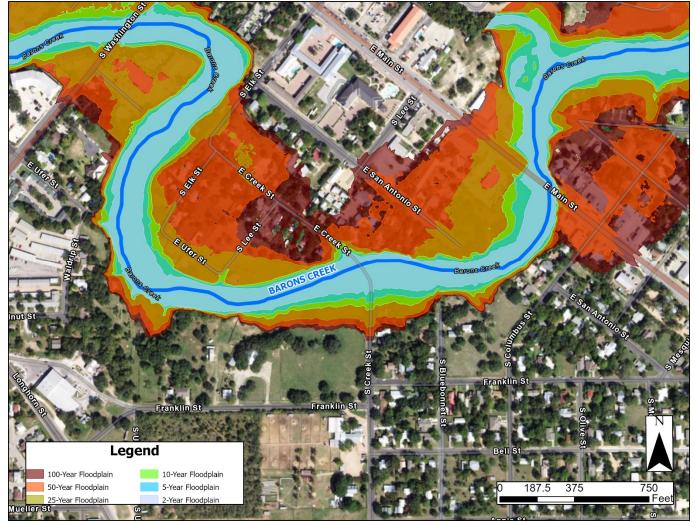

Storm Event (YR)	Water Surface Elevation (FT)	Overtopping Depth (FT)
2	1,648.58	3.58
5	1,651.68	6.68
10	1,654.20	9.20
25	1,659.82	14.82
50	1,662.34	17.34
100	1,663.91	18.91

Table 1: Peak Flow Rates

The road elevation is approximate elevation 1,645 feet, which is lower than the 2-year storm maximum water surface elevation. Thus, the existing crossing provides less than 2-year level of service. The roadway has an average daily traffic count of 885 and, according to the City, this is an important north-south connector street. The existing inundation map for each of the 2-, 5-, 10-, 25-, 50-, and 100-year frequency storm is presented in **Figure 2**.

Figure 2: Existing Condition Flood Risk

Proposed Improvements

Alternatives evaluated included cleaning the existing structure to remove significant sediment blockages, adding box culverts to increase capacity, and replacing the existing box culverts with a bridge. A summary of the results is presented in **Table 2**.

	Proposed Improvement					
Improvement ID	Culvert Improvement	Roadway Improvement	Overtopping Event			
Clean Out	Desilt existing RCBs	-	2-YR			
4-8x7RCB	Additional 8'x7' RCB barrel	-	2-YR			
Road Raise (10 year)	-	Raise to 1658.50 feet	25-YR			
Road Raise (100 year)	-	Raise to 1665.50 feet	>100-YR			

Table 2 – Summary of Results

Due to the depth of overtopping and because overtopping is dominated by the channel capacity and flow depth rather than culvert capacity (the road and culvert do not act as a dam causing overtopping) desilting the existing structure and addition of conveyance (additional box culverts) do not increase the level-of-service (i.e. reduce flood risk) for this crossing. Therefore, alternatives to raise the elevation of the roadway were considered. Those alternatives included raising the road to increase the level of service to safely pass the 10-year and 100-year events. Initial results were discussed with Mr. Bonn and the 100-year bridge (corresponding to 24-hour rainfall depth of 11.93 inches) was determined to not be feasible due to the configuration of the road as well as the number of adjacent privately owned parcels and structures. The City determined the 10-year event (corresponding to a 24-hour rainfall of 6.46 inches) is feasible, will provide significant safety and mobility improvements, and would be supported as a potential FMP.

The 10-year road raise alternative will require local channel modifications to offset rises in the 100-year water surface elevation. Those improvements include widening the channel from the road crossing to a point approximately 225 feet upstream with limited downstream improvements to tie into the existing channel.

Estimate of Probable Cost

The capital cost estimates for the flood mitigation alternative are based on previous expereince with similar project and unit costs and reviewing bid tabulations. The opinion of probable construction costs is an AACE Class 4 Estimate with an accuracy range of -20 to +30 percent. Total project costs include anticipated costs for final design, construction inspection, and easement acquisition. The opinion of probable construction cost was developed for elevation of the roadway above the 10-year storm event at a roadway deck elevation of 1,658.5 feet. The total construction cost is approximately \$1,613,000 and the total estimated project cost is approximately \$2,027,000.

Project Constraints

The purpose of identifying constraints early is twofold. The first is to confirm there are no unusual obstacles to implementation that would make a project not feasible. The second is an effort to identify and capture total project costs to minimize cost increases and delays in implementation. Potential constraints include environmental permitting, utility conflicts and relocations, right-of-way acquisition, and constructability.

As noted above, elevating the roadway will require channel modifications to mitigate potential increases in the 100year water surface elevation. Because this is an existing crossing it is anticipated that the modifications would be eligible to be permitted under a U.S. Army Corps of Engineers (USACE) Nationwide Permit (NWP) 14 for linear transportation projects. NWPs have thresholds for maximum disturbances such as excavation and fill within Waters of the United States as well as other cultural and environmental permitting requirements. If the thresholds are exceeded USACE may require public notification, mitigation, and potentially could require an individual permit. There are no known threatened or endangered species or previously identified cultural resources present in the project area.

Preliminary channel modifications and mitigation are based on HEC-RAS cross-section data and LiDAR topographic data and therefore lack the level of detail that will be included in final design; however, based on preliminary modeling the increases can be mitigated. Preliminary design indicates the bottom of the flood channel will need to be approximately 75 feet wide and will extend 225 feet upstream of the road.

Final design will include refinements to the selected alternative and hydraulic models based on survey. It is recommended final design include considerations such as natural channel design in the development of the final mitigation design. Natural channel design considerations should include preserving the existing low-flow channel or constructing an inset flood bench (multi-stage channel) to replace the low flow channel if needed, using natural channel boundary materials such as rock and boulders to provide grade control or erosion protection, and site restoration using native grasses, understory plants, and trees. These features will preserve/mitigate impacts to the natural functions of the channel necessary for permitting, preserve the existing character of the creek, and reduce or eliminate the need for long-term maintenance.

The project may require localized utility adjustments to accommodate the design and construction of the roadway improvements but nothing that is atypical for this type of project. There is at least one driveway that will need to be adjusted to tie into the new road and an easement (fully inside the 100-year floodplain) will be required for the channel modifications.

Benefit Cost Analysis

The TWDB Benefit Cost Calculation tool was used to develop pre- and post-project damage estimates and the FEMA BCA Toolkit was used to annualize those costs over a 30-year project life. The project is primarily focused on accessibility and the pre- and post-project damage estimates reflect the impacts of detours, delayed emergency access, and damage to the roadway and structure. The project benefits are the difference between the pre- and post-project damages annualized over the life of the project. The average daily traffic count was sourced from the Texas Department of Transportation, System Support Branch's TPP District Traffic Database. Expected damages were calculated with recurrence intervals at the 5-, 10- and 100-year storm events. Overtopping Impact (duration) was assumed to be 12 hours per 1-ft of inundation. The TWDB tool estimated benefits due to these factors are approximately \$719,200 with annualized benefits of \$301,960 from the FEMA BCA Toolkit. TWDB's tool includes other project benefits which, for this type of project include the residual value of the investment and environmental benefits. The TWDB tool estimates the residual value of the investment at \$79,620 and the environmental benefits at approximately \$268,900.

The Benefit Cost Analysis (BCA) generated a Benefit Cost Ratio (BCR) of 0.3. It is important to note that the environmental benefits identified above assume the natural channel design/riparian corridor elements recommended above are included in the final design. If those benefits are not realized the BCR will be reduced to 0.2.

No Negative Impact

In accordance with the *TWDB Technical Guidelines for Regional Flood Planning*, "No Negative Impact means that a project will not increase flood risk of surrounding properties. Using the best available data, the increase in flood risk must be measured by the 1 percent annual chance event water surface elevation and peak discharge. It is recommended that no rise in water surface elevation or discharge should be permissible and that the analysis extent must be vast enough to prove proposed project conditions are equal to or less than the existing conditions."

Mitigation Measures

Table 3 presents the results of the pre- and post- 100-year water surface elevations for the culvert cleanout, additional box culvert, and the elevation of the roadway above the 10-year flood depth with and without mitigation measures. As shown, structural improvements to the crossing without mitigation will result in a maximum rise in the 100-year water surface elevation of 0.67 feet at Station 27210. Model results including the proposed mitigation show there will be a minor decrease in the 100-year water surface elevation for a short distance upstream and downstream of the crossing. The lack of visible post-project 100-year floodplain in **Figure 3** reinforces the fact that it is overlaid entirely by the pre-project floodplain.

This memorandum is prepared to serve as certification of no negative impact for the Creek Street Roadway Improvements project. As the project is advanced the impact analysis should be updated to reflect the final design and to confirm no negative impacts.

Recommendation

Based on the results of this evaluation, and with concurrence from the Sponsor, we recommend the RFPG consider including the Creek Street Improvements as a new FMP in the Amended Plan.

TOTAL OPINION OF PROBABLE CONSTRUCTION COSTS

The Engineer has no control over the cost of labor, materials, equipment, or over the Contractor's methods of determining prices or over competitive bidding or market conditions. Opinions of probable costs provided herein are based on the information known to Engineer at this time and represent only the Engineer's judgment as a design professional familiar with the construction industry. The Engineer cannot and does not guarantee that proposals, bids, or actual construction costs will not vary from its opinions of probable costs.

NOTES:

1 FNI OPCC classified as an AACE Class 4 Estimate with accuracy range or -20 to +30.

This workbook has been designed to work in conjunction with FEMA's BCA Toolkit v6.0 to calculate the Benefit-Cost Ratio (BCR) of flood risk management projects for the Texas Water Development Board (TWDB).

The BCA Input Workbook is designed to help collate the necessary input data and to calculate the Baseline (Before Mitigation) and Project (After Mitigation) Damages. These damages are then input into the FEMA BCA Toolkit to calculate the Project benefits.

Instructions on how to download and install the FEMA BCA Toolkit v6.0 can be found here. Please refer to Model Instructions for detailed instructions on how to use this workbook. Input cells are highlighted green.

The TWDB BCA Input Workbook calculates benefits from the following benefit areas, which will be input into the BCA Toolkit:

Structure damages & associated loss of function Reduction in street flooding Utility loss of function Agricultural damages Low water crossings replacements

The following benefit areas are calculated entirely in the BCA Toolkit: Critical facility loss of function

The following benefit areas are calculated entirely in the TWDB BCA Input Workbook:

Recreation benefits Water supply benefits Environmental benefits of green infrastructure Residual value of investment

Project Name	Creek Street and Barrons Creek
Project Region	Region 10
Project Type	Drainage Improvement
Start Construction Year	2023

Input up to 3 Recurrence Intervals for which you have water level (H&H) data.

2024

At least 1 Recurrence Interval must be the 100-year storm.

Recurrence Intervals must be input in decreasing order of likelihood (i.e., 50-year storm before 100-year storm).

No No No Yes

No No No No

Recurrence Interval 1	5 year storm	
Recurrence Interval 2	10 year storm	
Recurrence Interval 3	100 year storm	

Types of Project Impacts

End Construction Year

Residential Structure Damage Reduction
Commercial Structure Damage Reduction
Critical Facility (Police, Fire, Hospital) Loss of Function Reduction
Reduction in Street Flooding
Utility Outage Reduction
Agricultural Damage Reduction
Water Supply Benefits
Recreation Benefits

Does this project include Green Infrastructure elements? Does this project replace a low-water crossing?

Input water levels and detour information in the 'Flooded Streets' sheet; Damage totals will be shown in 'Total Impacts'

Yes Input acreage of green infrastructure elements in 'Other Inputs' sheet; benefit totals will be shown in 'Total Impacts' Yes Input water levels in 'Low Water Crossing' sheet; Damage totals will be shown in 'Total Impacts'
